# All to Valencia Aquaculture Europe 2025

Aquaculture Europe has become the one meeting point for the whole European aquaculture sector for many years now, and this is especially the case for this event in Valencia with its inspiring theme for us all "**Aquaculture for everyone**". No doubt that aquaculture is a key provider of healthy and sustainable seafood worldwide. In Europe, Spain is exemplary on how it has developed a variety of marine and freshwater productions, integrated in their environment, and recognized by society. Yes, aquaculture is for everyone, and everyone has to acknowledge its importance and the multiple services it provides!

Thus, the European Aquaculture Society warmly invites the entire aquaculture community—scientists, industry leaders, policy makers, producers, educators, and students—to Aquaculture Europe 2025, here in Valencia, Spain**.** From cutting-edge technologies to sustainable practices, Aquaculture Europe 2025 will be a vibrant platform to share knowledge, forge partnerships, and explore how aquaculture can meet global food, climate, and societal challenges.

What will you get in Valencia?

- A top-tier scientific program covering all aspects of aquaculture research and innovation, with 40 Scientific sessions covering all disciplines, systems, species – this is more and more exciting from year to year, sometimes even difficult to choose which session attend! We have received more than 840 abstracts, which will be showcased through e-posters and more than 500 oral presentations
- Inspiring plenary sessions by key experts - Carlos Duarte on regenerative aquaculture, Elisabetta Giuffra on leveraging the value of functional genome annotations and Joan Riera on seafood consumption.
- An Industry forum, an Innovation forum, an FAO workshop on its "Guidelines for Sustainable Aquaculture" and a stimulating panel/roundtable organised by the Network for Women in Aquaculture.
- A fantastic international trade show where you will see the latest innovations available on the market
- Field visits to key aquaculture sites and research facilities
- Unique networking opportunities—from expert panels to wonderful tapas evenings!

As always, Aquaculture Europe is not just a conference—it's the meeting point for the entire European and international aquaculture family. Whether you're looking to present research, discover solutions, or shape the future of our blue food systems, AE2025 is where it all comes together. We welcome 2500 attendees from all over the world, including you!

This would not have been possible without be the involvement of the Next Generation Marine Science programme, ThinkInAzul, the Steering committee chaired by Jaume Perez-Sanchez (CSIC), the program co-chairs Diego Mendiola (Caviar Pirinea) and Martin Føre (SINTEF), and the local organizing Committee. They all put in tremendous efforts to make this conference a success, together with the EAS Home Office and our long-standing partners Mario Stael and John Cooksey.

A big thanks also for the support of our local partners, national and regional governments, our Gold Sponsor Skretting, our Silver Sponsors Biorigin, Dibaq, HIPRA, INVE and miXscience, Session Sponsor CTN and our media partners, with a special mention for MisPeces who do such excellent coverage of all our events.

The week will be too short, but so good!

Marc Vandeputte
EAS President

# ABSTRACTS

# INFECTION WITH MOBILE STAGES OF SALMON LICE AND CALIGUS ELONGATUS IN A SALMON FARM NETWORK

Gunnvør á Norði*, Birgitta Andreasen, Kirstin Eliasen, Tróndur Kragesteen, Signar P. Dam, Lars A. Hamre

*Firum
FO-430 Hvalvík
Faroe Islands
E-mail: gunnvor@firum.fo

In Atlantic salmon aquaculture, understanding the infection dynamics of sea lice is critical for sustainable management. For salmon lice *(Lepeophtheirus salmonis*) the most common infection pathway is direct infection through the planktonic copepodite stage. However, the high level of handling of the farmed fish where a portion of the mobile lice fall off might induce an indirect infection pathway where mobile lice survive and successfully find a new host. The other sea lice species that affects farmed salmon in the north Atlantic is the generalist *Caligus elongatus* which has been found on more than 80 fish species. This species has different behavioural traits than the salmon lice and the relative contribution of direct and indirect infection pathways to the overall infection pressure on farmed fish is not well understood.

In this study indirect and direct infection pathways of salmon lice and *C. elongatus* were investigated by analysing comprehensive sea lice monitoring data from the Faroese salmon farming industry, covering more than 1200 cage deployments. Indirect infection was identified when mobile or adult lice were found on newly deployed fish before development from a copepodite was possible according to temperature-based development models for the two species.

This approach provided a detailed examination of indirect infection dynamics in an operational farming environment. Preliminary observations suggest a notable difference between the two lice spices, with indirect infection substantially more prominent for *C. elongatus* than salmon lice.

# SOCIAL ACCEPTANCE OF BALTIC SEA BLUE MUSSELS

Maya Miltell*

SUBMARINER Network for Blue Growth
Email: mmi@submariner-network.eu

**Introduction**
The Baltic MUPPETS project is an investment in a blue bioeconomy that aims to deliver economically and environmentally viable businesses with a positive socio-economic impact. The project sets out to create an entirely new value chain based on small blue mussels, enabling a new circular economy in the Baltic Sea region and supporting mussel farmers throughout Europe to develop, diversify and scale their existing businesses.

The development of sustainable aquaculture is a current political issue and it is considered a future industry with great potential. Production of aquaculture-based products such as mussels is also labor-intensive and can therefore contribute to increased employment rates, especially in sparsely populated areas. A fully developed mussel production could, for example, create complementary jobs for local fishermen, but also facilitate changes of ownership and new recruitment through the expansion, diversification and long-term profitability. In addition, depending on which end product that is developed, a number of other industries/occupational categories can be activated. For instance, within fishing or food tourism.

Through cultivation, harvesting and efficient marketing, the Baltic blue mussel can thus help to return nutrients from sea to land and at the same time transform access nutrients into a sustainable job-creating natural resource. Put in another way, mussel farming could provide a way to integrate environmental objectives with economic and socio-economic goals in order to advance and strengthen the three interdependent pillars of sustainable development.

Using three case studies (ECOPELAG in Sweden, Wittrup Seafood in Denmark and Kieler Meeresfarm in Germany), the business cases are explored, including bottlenecks such as legislative and social acceptance.

**Site-selection and technology for social acceptance**
When establishing a mussel farm it is important to consider the public view when selecting the site and technology. All farmers in Baltic MUPPETS use submerged farming solutions, meaning the infrastructure is also less visible over the surface. This can increase the acceptance. Similarly, it is important to choose sites that inflict as little as possible with the public, both ecstatically and recreationally, as well as other industries.

**Working with the public**
It is important to early gain the approval of the public when establishing a mussel farm. Inclusion in planning processes, site-selection, etc. can evoke a feeling of influence and lower negative perception.

The public perception of mussel farms has been a challenge for some mussel farmers in Denmark. The BONUS Optimus project showed the Danish perception was generally more negative than the German one. This might be due to more experience as mussel farming is not equally established in Germany. Further, there has been much debate about mussel farming and fishing in the media. However, this is recently changing as the political circumstances are promoting mussel farming more whilst banning trawling. In Kiel, Kieler Meeresfarm has worked a lot with public engagement in the farms, and putting a lot of effort into education. Locals can “adopt a line”, giving some ownership and increasing acceptance. Also, working together with leisure boat associations to highlight seasonal opportunities for collaboration highlights the non-competitive nature of the farm and adjacent industries. In eastern Sweden, ECOPELAG is working closely with the municipality to gain approval by the public, e.g. by cooperating with the local “Nature Room”, a public nature education initiative. Here they mainly focus on teaching about the benefits the farm can give to the local environment and biodiversity.

**Bottlenecks for social acceptance**
A bottleneck for the farming of mussels in the Baltic Sea is the general scepticism of the water quality and product safety. Without approval of the products, the business models are not sustainable as the demand is reduced. For this, it is important to be transparent about quality testing and assurance. This can be difficult depending on the legal testing requirements, and too rigorous or unsuitable processes can hinder quick communication about quality, e.g. if tests need to be done in certain laboratories and waiting times are long.

# AUTOMATED INDIVIDUAL FEEDING INTAKE QUANTIFICATION IN EUROPEAN SEABASS (*Dicentrarchus labrax*) USING MULTI-MODEL COMPUTER VISION AND FISH RE-IDENTIFICATION

A.H. Abas[1*], H. Zouine[1], A. Vergnet[1], M.M. Ziaei[2], Y. Ceylan[3], P. Císař[2], F. Allal[1], M. Vandeputte[1]

[3]Faculty of Aquatic Sciences, Istanbul University, Istanbul, Türkiye
*E-mail : abdul-hawil.abas@inrae.fr

**Background and Objectives**

Precision feeding in aquaculture requires accurate monitoring of individual fish feeding behavior to optimize feed conversion ratios and reduce environmental impact. Traditional methods for assessing feeding intake in European seabass (*Dicentrarchus labrax*) rely on individual compartments that induce stress or bulk measurements that fail to capture individual variations critical for selective breeding and personalized nutrition strategies. This study presents a novel automated system for real-time individual feeding intake quantification using advanced computer vision and fish re-identification technologies.

**Methods**

We developed a comprehensive two-pass computer vision pipeline integrating four specialized YOLO models: pellet detection, open mouth detection, fish eye tracking, and fish face identification. All of the models are built on yolo11n except the fish face detection which use a yolo11n-obb. Manual annotations are done with Label Studio 1.16.0 and trained on NVIDIA A40 GPU provided by MARBEC GPU. The system employs a custom CNN-based re-identification network trained on fish-specific embeddings to maintain individual fish identity across video frames (Figure 1.). The whole pipeline include: (1) pellet disappearance tracking with configurable temporal windows, (2) proximity-based feeding event detection linking pellet consumption to open mouth behavior, (3) persistent fish tracking using eye detection as anchor points, and (4) dynamic conflict resolution for accurate individual attribution. The system processes video data through a first pass for global fish identity establishment, followed by a second pass for real-time feeding event detection and attribution.

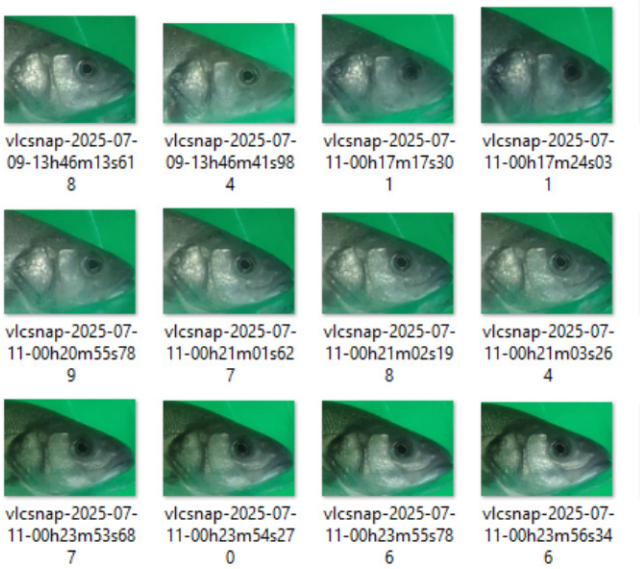

**Figure 1.** Examples of training dataset for fish re-identification

*(Continued on next page)*

## Results

Testing on European seabass feeding trials demonstrated robust performance in individual fish tracking and feeding event detection (Figure 2). The system successfully tracked multiple fish simultaneously, maintaining individual identities. Feeding events were accurately detected by correlating pellet disappearance (tracked over minimum 5 frames) with open mouth detection within configurable proximity thresholds (200 pixels). The re-identification network achieved reliable fish recognition using normalized embeddings with Euclidean distance metrics, enabling consistent individual attribution across extended observation periods.

## Discussions and future plan

This automated system represents a significant advancement in precision aquaculture. Currently, there are several errors including too many unknown fish and pellet and eye detection confusion. We are trying to improve the identification by using a deeper CNN architecture and refine the training dataset. We will try also to run this technology on a longer video. We are also developing a whole-body identification and key frame feeding event detection.

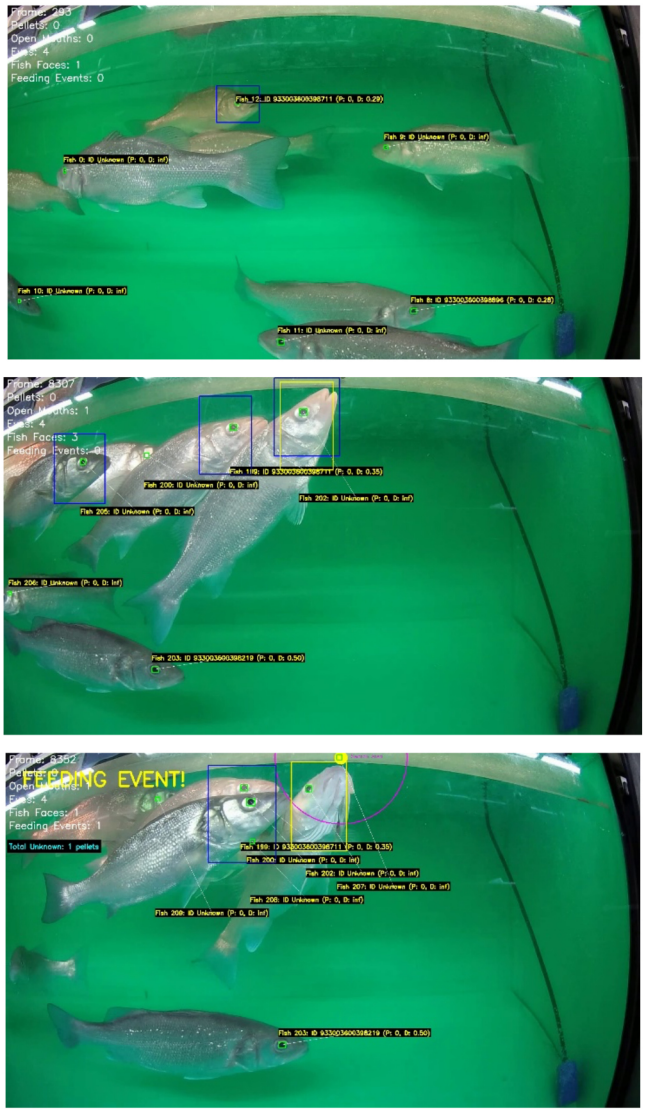

**Figure 2.** Screenshots of the output video. Blue box represents the fish face detection who feed the re-identification model. Yellow box represents the open mouth detection. Green box is the eye tracker with a white line to the tracker id (fish+numer), real ID, P which is the pellet eaten and D which is the Euclidean distance for identification. Feeding event are triggered by the disappearance of tracked pellet and the presence of open mouth in the search area (magenta circle). The feeding event then attributed to the nearest tracked eye

# PROTEOMIC INSIGHTS INTO TAURINE-INDUCED CHANGES ON EUROPEAN SEA BASS MYOTUBES

Roger Solà*[1], Manel Montblanch[1], Isabel García-Pérez[1], Mar Vilanova[2], Marta Vilaseca[2], Josep Chillarón[1], Daniel Garcia de la serrana[1], Joaquim Gutiérrez[1], Josefina Blasco[1], Miguel Martin-Perez[1]

E-mail: rogersola@ub.edu

**Introduction**

European sea bass (*Dicentrarchus labrax*) is one of the most commercially valuable species in the Mediterranean aquaculture. However, the use of highly substituted diets for European sea bass is hampered due to the high carnivorous habits of this species. The non-protein amino acid, taurine, has been previously reported as a potential dietary supplement in fish aquaculture, enhancing both growth and antioxidant capacity (D. Montero et al., 2023; P. Salze and Allen Davis, 2015). Here, to better understand the signalling response triggered by taurine in muscle, proteomic and phosphoproteomic analyses were carried out on cultured myotubes from European sea bass.

**Methodology**

European sea bass juveniles (10 ± 2 g of body weight) provided by Culmarex (Mallorca, Spain) were maintained in our indoor facilities at the University of Barcelona. Muscle cells were extracted from 11-12g of white epaxial muscle from juveniles and cultured in quadruplicate (n=4) for 13 days until myotube development stage (García-Pérez et al., *under review*). Cells were treated 24h with 10mM taurine (showed no effects on cell viability) and protein extracted with 8M urea buffer containing a mix of proteases and phosphatases inhibitors. Samples were reduced, alkylated, and digested with LysC and trypsin. Digested peptides were desalted with reverse phase C18 columns, keeping an aliquot for proteome analysis and using another aliquot for phosphopeptide enrichment by IMAC using Fe-NTA magnetic beads. Data acquisition was performed by nano LC-MS/MS using Evosep One chromatograph coupled to an Orbitrap Eclipse mass spectrometer with DDA methods. MaxQuant software was used to identify and quantify the proteome and phosphoproteome using European sea bass database from Uniprot, whereas Perseus and R software were used for bioinformatic analyses.

**Results and discussion**

We quantified 2643 proteins, of which 267 (10.1%) showed significant changes in abundance between taurine and control groups. Hierarchical cluster analysis of z-score normalized changes in proteome abundance allowed to discriminate between control and treatment groups (Fig.1a). Downregulated proteins upon taurine treatment were enriched in gene ontology biological process terms (GOBP) related to cell development (Fig.1b), while mostly protein translation processes were upregulated. We identified 7259 phosphosites, of which 1179 (16,2%) displayed significant differences in intensities between the two groups (Fig.2). Several targets of the mTOR signalling pathway showed increased phosphorylation upon taurine treatment, such as AKT, 4EBP1, and EIF4EBP1, as well as transcriptional factors (e.g., EIF3A) involved in protein synthesis. These findings support a proteinogenic stimulus of taurine in muscle cells by enhancing mTOR signalling and ribosomal activity, thus indicating its potential as a dietary additive for stimulating muscle growth in European sea bass.

*(Continued on next page)*

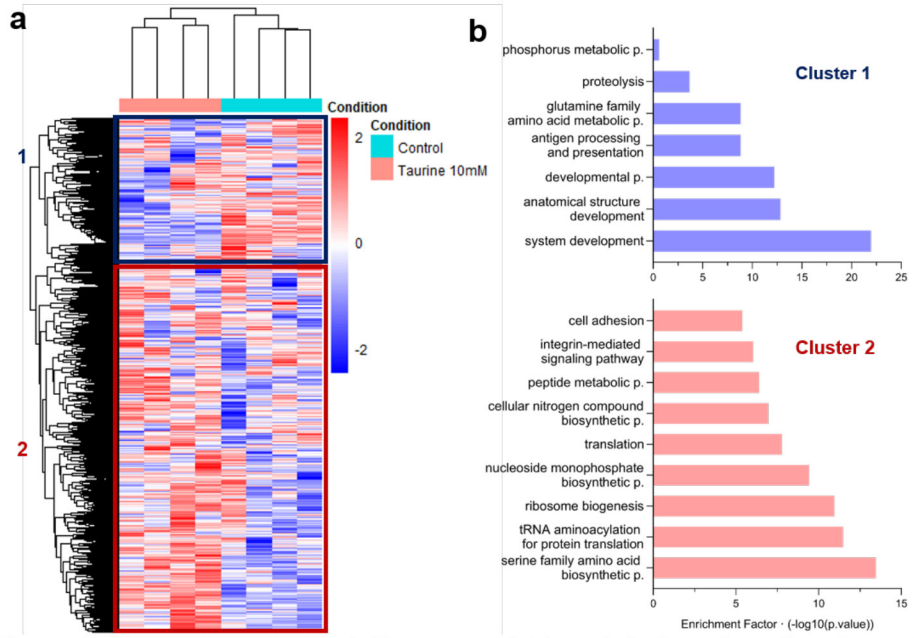

**Figure 1**: Proteomic analysis. a) Heatmap and hierarchal clustering of total proteins detected. b) Significantly enriched GOBP terms from main clusters of heatmap.

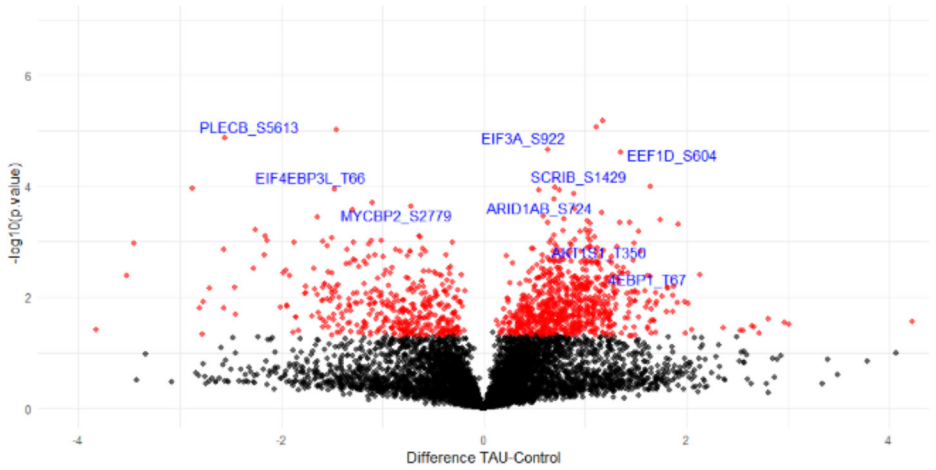

**Figure 2**: Volcano plot comparing taurine and control group from phosphoproteomic data. (n=3, t-test p-value < 0.05). Highly significant phosphosites involved in mTOR signalling are indicated.

# HOW INPUT DATA QUALITY AFFECTS AQUACULTURE ZONING

A. Abramic*, S. Kaushik, L.M. Pulido Santiago, A.R. Trujillo Pino, N. M. Monzón López, C. Andrade, N. Nogueira, Y. Fernandez-Palacios, Ricardo Haroun

*ECOAQUA University Institute
University Las Palmas de Gran Canaria
Parque Tecnológico Marino Taliarte
Las Palmas, Spain
e-mail: andrej.abramic@ulpgc.es

**Introduction**

In the framework of the PLASMAR (2017-2021) and PLASMAR+ (2021-2023) projects, we developed a multi-parameter spatial analysis to assess the suitability of marine areas for aquaculture development in the Canary Islands and Madeira archipelago. Zoning analyses integrated diverse criteria structured as marine environmental conditions, conservation targets, oceanographic potential, coastal uses, and maritime operational sectors. The results have been presented on Aquaculture Europe 2021 and directly applied to inform the Maritime Spatial Planning (MSP) processes in both regions, supporting evidence-based decisions for aquaculture site allocation.

**Methodology & results**

Following, the ReMAP project (2022-2025) applied the MSP Data Framework (Technical Expert Group on Data for MSP, 2023) to develop an Input Data Module. This tool allows for a systematic evaluation of the spatial data underpinning MSP, focusing on thematic availability, transparency, quality, coverage, and resolution. We applied the module to assess the input datasets used in the aquaculture suitability analyses for Madeira and the Canary Islands. The findings reveal how variations in data quality, completeness and coverage can significantly influence the outcomes of spatial planning and, ultimately, the identification of suitable areas for aquaculture.

**Conclusion**

This is the first analysis of its kind that shifts attention to how we *feed* the model—examining the input data itself. While discussions around spatial models often focus on their internal mechanisms or just on delivered "model" results we rarely scrutinize the type and quality of data entering the model and how that input shapes the final results. This approach brings a new level of transparency and critical understanding to the modelling process in maritime spatial planning.

As one of 10 ReMAP modules, developed for MSP evaluation and monitoring, the Input Data Module is as an open-access, open-source tool. It is easy to use, designed as an intuitive auto-assessment system that simplifies the evaluation process while decreasing complexity and increasing reproducibility. The tool is immediately available to the aquaculture and MSP community for direct use, adaptation, and integration into planning processes following this presentation.

# NUTRIENTS' DIGESTIBILITY AND INTESTINAL MORPHOLOGY OF EUROPEAN SEABASS AND GILTHEAD SEABREAM FED DIETS WITH BLACK SOLDIER FLY OIL UNDER TWO REARING TEMPERATURES

D. Acebes*, T. Sá, D. Marques, V. Sousa, P. Canada, S. Magalhães, D. Murta, L.M.P. Valente, A. Basto

CIIMAR/CIMAR LA – Centro Interdisciplinar de Investigação Marinha e Ambiental and ICBAS – Instituto de Ciências Biomédicas de Abel Salazar
Universidade do Porto
Porto, Portugal

*dacebes@ciimar.up.pt

**Introduction**

The growing demand for high-quality seafood – driven by population growth and increasing consumer awareness of the health benefits of fish consumption – is propelling aquaculture expansion, which in turn increase the need for aquafeed and sustainable raw materials. Black soldier fly larvae oil (*Hermetia illucens*, BSFLO), rich in lauric acid (C12:0; 30-70%), a medium-chain saturated fatty acid (SFA), is gaining attention for its potential functional properties. However, water temperature can significantly affect the digestion and absorption of dietary lipids in fish. This is particularly relevant for lipid sources rich in SFA, which generally have higher melting points than their unsaturated counterparts of the same chain length. As a result, temperature-dependent changes in the physicochemical properties of dietary lipids may influence their bioavailability and utilization by fish in cold water conditions. Therefore, this study aimed to explore the impact of the dietary BSFLO inclusion on macronutrient and fatty acid digestibility, as well as intestinal morphology, of European seabass (*Dicentrarchus labrax*) and gilthead seabream (*Sparus aurata*) – two key species in Mediterranean aquaculture – reared at 15 °C and 23 °C, to simulate average seasonal conditions (winter and summer) in the Mediterranean.

**Material and methods**

A control diet (CTRL) was formulated with 6% fish oil and 5% poultry oil (PO). Three other experimental diets were formulated to include 1.7%, 3.4% and 5.2% of BSFLO (Entrogreen® - Ingredient Odissey S.A), at the expense of PO (BSFLO1.7, BSFLO3.4 and BSFLO5.2, respectively). All experimental diets contained 1% $Cr_2O_3$ as an inert marker. These diets were tested in triplicate groups of seabass and seabream, maintained under two temperature conditions (15 °C and 23 °C) in a recirculating aquaculture system (RAS) with sedimentation columns for faeces collection. Fish were fed to apparent satiation three times daily and faeces were collected daily and stored at -80 ºC. After freeze-drying, faecal chromium, crude protein, total lipids, crude energy, and fatty acids levels were determined, and their apparent digestibility coefficients (ADC) were calculated. In addition, at the end of digestibility trials, a histomorphometric evaluation of the fish anterior intestine was performed.

**Results**

Dietary inclusion of BSFLO did not impact the anterior intestinal histomorphology of either seabass or seabream. However, water temperature significantly influenced European seabass cross-sectional-area and -perimeter, as well as the thickness of the muscularis, submucosa, and lamina propria, villus length and the total number of acid goblet cells, which were significantly reduced at the lower temperature. These intestinal changes were associated with a slight reduction in protein digestibility from 91% at 23 ºC to 90% at 15ºC. Total lipid ADC values remained similar between temperatures, but the digestibility of SFA decreased at 15 °C (93% vs. 98%), resulting in lower energy ADC values (81% at 15 ºC vs. 83% at 23ºC). BSFLO dietary inclusion had no impact on seabass macronutrient, fatty acid, or energy digestibility, despite the higher SFA content in BSFLO diets. In contrast, in seabream, the digestibility of SFA was significantly higher in fish fed BSFLO3.4 and BSFLO5.2 diets than those fed the CTRL diet (95% vs. 97%), regardless of water temperature. Macronutrients, fatty acids and energy digestibility remained similar at 15ºC and 23ºC. Likewise, temperature had a minimal effect on the intestinal structure, with the only changes observed being a reduction in thickness of the muscularis and a lower number of acid goblet cells at 15ºC.

*(Continued on next page)*

**Discussion and conclusion**

The results of this study highlight species-specific responses to dietary BSFLO and water temperature in European seabass and gilthead seabream. While BSFLO inclusion had no significant effects on intestinal histomorphology or nutrient digestibility in either species, water temperature played a more critical role in seabass, where rearing lower temperatures (15 °C) led to structural intestinal changes and a slight reduction in protein and SFA digestibility. In contrast, seabream exhibited a similar digestive function at 15ºC and 23ºC and even furthered from improved SFA digestibility with BSFLO dietary inclusion. These findings suggest that BSFLO is a viable lipid source for seabream and can be effectively used in aquafeeds without compromising nutrient absorption. However, long-term pilot studies are needed to validate these results in seabream and assess the physiological consequences observed in seabass, namely the potential impact on growth performance and fish health. In addition, complementing digestibility and histological evaluations with other types of analyses, such as digestive enzyme activity or gene expression profiling, would help to better understand the mechanisms underlying these species-specific responses.

# BEYOND THE SPAWN: EPIGENETIC AND TRANSCRIPTOMIC FOOTPRINTS OF SEASONAL MANIPULATION IN ATLANTIC SALMON FRY

Anne-Catrin Adam*, Takaya Saito, Per Gunnar Fjelldal, Marit Espe, Nicholas Andrew Robinson, Kaja Helvik Skjærven

Institute of Marine Research
P. O. Box 1870
Nordnes, 5817 Bergen (Norway)
E-mail: Anne-Catrin.Adam@hi.no

## Introduction

Manipulating spawning time doesn't just extend the breeding calendar - it initiates molecular responses that can shape the next generation. In aquaculture, altering environmental cues such as temperature and photoperiod to shift the spawning window is a well-established strategy to ensure year-round offspring production. While effective in practice, the broader biological consequences of this approach across generations remain insufficiently understood. Delaying spawning in Atlantic salmon reduced egg quality but had no effect on fecundity and improved fry size (Fjelldal et al. 2024). Manipulating spawning time also altered egg nutrient profiles, which may suggest potential impacts on offspring through metabolic programming (Skjærven et al. 2020; Skjærven et al. 2022). Saito et al. (2025) linked a manipulation of spawning time to altered DNA methylation profiles in salmon fry livers with potential implications for growth and development, however, little is known about how such reproductive interventions impact muscle growth. This study explores how extending the spawning season of Atlantic salmon - comparing delayed vs. normal spawning - impacts the nutritional, transcriptomic and epigenetic programming of both muscle and liver in first-feeding fry.

## Material and methods

Unfertilized eggs and first-feeding fry (~845 degree-days) derived from broodstock exposed to either normal or delayed spawning conditions were sampled. We analysed free and protein-bound amino acid profiles in unfertilized eggs and first-feeding fry to assess nutrient status and early metabolic regulation. RNA was extracted from muscle and liver of first-feeding fry for RNA-sequencing and genomic DNA for EM-sequencing to assess gene expression and methylation landscapes.

## Results

Preliminary results revealed a stronger transcriptional response in muscle than in liver of first-feeding fry, with an approximately fivefold increase in differentially expressed genes between the spawning groups, indicating a more pronounced tissue-specific response in muscle at this early developmental stage. In parallel, amino acid profiling of both eggs and fry showed distinct metabolic signatures between the spawning seasons, which are suggestive of compensatory adjustments in response to the nutrients supplied by the mother to the yolk. These metabolic shifts showed alignment with the gene expression changes. Across both tissues, differentially expressed genes were enriched in pathways related to energy metabolism, protein turnover, and one-carbon (1C) metabolism - key processes known to influence the methylation potential. Ongoing epigenetic analyses will provide insight into regulatory pathways affected by these molecular changes at early life stages.

## Discussion and Conclusion

These findings indicate that extending the spawning season modulates offspring development at both metabolic and molecular levels. Notably, delayed spawning resulted in larger fry, suggesting enhanced early growth potential despite reduced egg quality. This growth advantage may be linked to the transcriptional changes observed in muscle tissue, which appears particularly responsive to altered spawning conditions. By combining gene expression, amino acid profiles, and epigenetic data, this study provides a foundation for understanding how altered spawning timing shapes offspring physiology at multiple biological levels. This knowledge may support the refinement of spawning strategies and nutritional protocols to optimize robustness performance in commercial aquaculture.

**Introduction**
Monitoring immune responses in non-lethal epithelial tissue samples, combined with pathogen detection in environmental samples, is a powerful approach for diagnosing mucosal diseases in fish. This approach is particularly valuable in aquaculture and wildlife contexts, where sacrificing animals for testing is not feasible. We applied and evaluated this strategy in several case studies, including multifactorial gill disease in common carp (Cyprinus carpio) and gill disease in rainbow trout (Oncorhynchus mykiss), based on both diagnostic submissions and selected infection experiments. Other case studies included hyperpigmentation in common dab (Limanda limanda) and Fancy-Tailed Guppy Virus (FTGV) infection in guppies (Poecilia reticulata). Our aim was to assess the diagnostic value of epithelial immune profiling alongside the molecular detection of pathogens in both fish and their environment.

**Methodology**
Samples included gill biopsies, skin/gill swabs and water collected during natural outbreaks and experimental infections. These samples were stored at −20 °C prior to analysis. Pathogens were concentrated from the water samples using various filtration methods, and then detected via qPCR/RT-qPCR. Host immune responses were profiled using RT-qPCR or Fluidigm arrays and correlated with pathogen load and histopathological changes. In dab, hyperpigmented and normally pigmented skin samples from the same fish were compared using 16S metabarcoding and immune marker profiling. In guppies, samples from outbreak-associated and laboratory-raised populations were analysed for FTGV using virological and molecular assays, metabarcoding and immune profiling.

**Results**
Epithelial immune profiling revealed pathogen-class-specific signatures, with antiviral responses observed in viral gill diseases and proinflammatory profiles in bacterial infections. Gill swabs proved to be as reliable as biopsies for detecting these signatures. Water filtration at 0.20–0.45 µm enabled the sensitive detection of gill disease pathogens, often at the earliest stages of infection, and pathogen nucleic acids persisted in the environment after the removal of infected fish. In dab, however, no microbiome differences or antiviral responses were detected between hyperpigmented and normal skin, suggesting a non-infectious cause. FTGV was detected for the first time in Europe in outbreak-associated guppy populations. Partial genome sequencing revealed significant viral diversity; however, immune profiling was uninformative due to late, subclinical infection stages.

**Conclusions**
Measuring immune responses in epithelial tissues alongside environmental pathogen detection enables the early, non-lethal diagnosis of mucosal diseases in diverse fish species. This integrated approach can be used for differential diagnosis (e.g. viral versus bacterial gill diseases), surveillance (e.g. FTGV in guppies) and outbreak management, particularly in settings where post-mortem sampling is impractical. Our findings emphasise the effectiveness of combining immune profiling with environmental DNA/RNA detection for improving fish health monitoring in aquaculture and wild populations.

# USING THE LARVAL STAGES OF ATLANTIC SALMON AND ZEBRAFISH TO STUDY THE ANTIVIRAL AND IMMUNOMODULATORY EFFECTS OF 25-HYDROXYCHOLESTEROL (25HC) AGAINST TILAPIA LAKE VIRUS (TILV)

## Introduction

25-hydroxycholesterol (25HC) is an oxidised derivative of cholesterol that can be produced either enzymatically, via the action of cholesterol 25-hydroxylase (Ch25h), or through non-enzymatic pathways involving reactive oxygen species (ROS). In mammals, 25HC has been associated with the inhibition of viral entry into host cells, indicating a potential role in immune defence. However, its impact on antiviral responses in fish remains unclear. This study aims to investigate the influence of 25HC on viral infections and the immune response in the larval stages of zebrafish and Atlantic salmon, which are relevant to aquaculture, to demonstrate their potential in the search for new antiviral or immunomodulatory substances.

## Methodology

Atlantic salmon and zebrafish larvae were injected with 25HC into the pericardium, and two hours later were infected with Tilapia Lake Virus (TiLV). Additionally, we developed a new zebrafish knockout line with a five-base-pair deletion in the gene encoding cholesterol 25-hydroxylases (ch25hb-/-), using CRISPR/Cas9 gene editing. Larvae from both the ch25hb-/- and the ch25hb+/+ lines were infected with TiLV by intrapericardial injection. Viral load and the expression of immune-related genes were studied by RT-qPCR.

## Results

A significantly lower viral load was observed in Atlantic salmon and zebrafish larvae treated with 25HC compared to the control group. This suggests that 25HC treatment reduces viral entry and/or replication upon infection. Furthermore, we found that the expression of immune-related genes encoding proteins involved in the type I IFN pathway (e.g. *rig-I, irf3, irf7, mxa, isg15*) and pro-inflammatory cytokines (*il-1b, il-6*) as well as *ch25hb* was up-regulated in TiLV-infected fish, although almost no significant effect of 25HC treatment was recorded. In case of *ch25hb*$^{-/-}$ knock-out zebrafish, no notable differences in terms of development and survival were observed as compared to the *ch25hb*$^{+/+}$. Interestingly, upon TiLV infection, viral load was significantly higher in *ch25hb*$^{-/-}$ zebrafish compared to *ch25hb*$^{+/+}$ controls, which suggest that loss of *ch25hb* compromises the host's capacity to control TiLV replication. This observation was reinforced by gene expression analysis, which revealed a significant lower expression of multiple antiviral response genes in the *ch25hb*$^{-/-}$ zebrafish.

## Conclusions

This study provides new insights into the function of 25HC during viral infections in Atlantic salmon and zebrafish larvae. Pre-treatment with 25HC significantly reduced viral load in both fish species examined. Additionally, disruption of the ch25hb gene impaired the host's ability to control TiLV infection, highlighting the gene's role in antiviral defence. This shows that zebrafish can be used as a proxy for aquaculture-relevant species. Furthermore, Atlantic salmon larvae can be used to test the antiviral activity of substances in a similar capacity to zebrafish.

# SYSTEMIC DYSBIOSIS AS A CONSEQUENCE OF CARP EDEMA VIRUS INFECTION

**Introduction**
Carp edema virus (CEV) is a highly contagious pathogen affecting common carp (*Cyprinus carpio*). The virus causes koi sleepy disease (KSD), which is characterized by disturbances of the gill function, resulting in hypoxia, hyponatremia, and hyperammonemia. Our previous studies shown that CEV infection led to immunomodulation and activation of stress response. In the present study, we analyzed the impact of CEV infection on the gill, foregut and hindgut microbiota of the common carp.

**Methodology**
Gill and gut microbiota was analyzed by metabarcoding of bacteria 16S rRNA. Pathomorphological changes of the gill and gut tissues caused by CEV infection were assessed using HE staining. Expression of selected genes encoding proteins involved in antiviral, inflammatory and mucosal response as well as tight junction proteins was analyzed in studied tissues by RT-qPCR. Cortisol and glucose level was measured in blood plasma using ELISA and glucometer, respectively.

**Results**
Infected fish had mean $3.53x10^5$ viral DNA copies in gills, $1.4x10^2$ DNA copies in foregut and $1.49x10^3$ DNA copies in hindgut at 6 day post exposure. Infection induced increase in blood cortisol and glucose levels. Histopathological analysis of the gills demonstrated nearly complete occlusion of the intralamellar space with the accumulation of cellular debris and an infiltration of eosinophilic cells in CEV-infected fish. In gut only minor histopathological changes were recorded. CEV infection clearly impacted gill microbiota, resulting in increased number of bacteria, e.g. *Flavobacterium, Cetobacterium, Aeromonas, Pseudomonas.* In two studied parts of the intestines only in hindgut significant increase of bacteria genera (*Flavobacterium, Cetobacterium* and *Aeromonas*) was observed. Gene expression analysis revealed up-regulation of the expression of anti-viral *mxa, vig 1* and pro-inflammatory *il-1b* in gills, foregut and hindgut upon CEV infection. Among mucosal related genes, only *muc 5b* was up-regulated in gills of infected fish, while in case of genes encoding tight junction protein, expression of *cldn 7* was up-regulated in all studied organs, and expression of *cldn 23* and *cldn 30* was up-regulated in foregut and hindgut.

**Conclusions**
CEV infection induces stress and immune responses and ultimately disrupts microbiota by favoring bacterial growth, paving the way for secondary bacterial infection. Our study helps to understand the effect of CEV infection on the host microbiota and partly explains the mechanisms for occurrence of secondary bacterial infections related to KSD.

**Introduction**

Tilapia (*Oreochromis niloticus*) is a cichlid native to Africa and the Middle East, produced almost worldwide, with 12 species of commercial importance to date. Its global production has grown over the years, reaching a mark of 6.95 million tons in 2024 (FAO 2024; O Presente Rural 2025). In Angola, parasites in tilapia and the diseases they cause have not been studied to date. However, with the widespread and intensified tilapia farming throughout the country and increased consumption, research on the parasitic fauna of tilapia produced in Angola is necessary as a basis for controlling parasite populations, preventing the occurrence of parasitic diseases, and producing safe food. This is a pioneering study in the detection, identification, and assessment of parasite load in tilapia farming in Angola. It contributes to raising awareness about fish health management among producers and aquaculture potential, service providers, and researchers, strengthening the framework for sustainable production.

**Materials and Methods**

A total of 241 specimens of Nile tilapia, clinically healthy, including fingerlings, juveniles, and adults, were randomly collected during September 2024–January 2025 and April–July 2025 in five private tilapia production units (named A, B, C, D & E) of Huambo, Angola, for parasitological analysis, following the sampling procedures described by Ishikawa *et al.,* 2016. The fish were analysed for the detection of ecto and endoparasites using both macroscopic and microscopic methods. Externally, the skin, fins, mouth, eyes, operculum, and gills were examined with the naked eye. Internally, the heart, muscles, gallbladder, stomach, and intestines were inspected. After the samples were collected and the prepared slides were analyzed microscopically (Guzman *et al.,* 1988; Menezes 2000; Mitiku 2021; Pinacho-Pinacho *et al.,* 2023).

**Results**

From the 241 fish examined, 61 were infested with one or multiple parasites belonging to different genera. Different types of parasites were detected, both in internal organs and on the external surface of the body. The most prevalent parasite group was Monogenea (represented by the genera Gyrodactylus, Dactylogyrus, and Cichlidogyrus), with a prevalence of 11.2% detected in the skin and gills. This was followed by Digenea, with 9.5% detected in the intestine. The least prevalent group was Nematoda (larvae and eggs), with 4.6% detected in the intestine and gallbladder. (Table 1).

Table 1. Groups of parasites detected, infested organs and respective prevalence in five fish farms (named A, B, C, D and E) studied.

| Group | EF | PF | P (%) | Organs | Fish farm |
|---|---|---|---|---|---|
| Monogeneans | 241 | 27 | 11.2 | Gills, Skin | A, B, C, D & E |
| Digeneans | 241 | 23 | 9.5 | Gills, Skin | A, B, C, D & E |
| Nematode | 241 | 11 | 4.6 | Intestines, gallbladder | B, C, D & E |
| Total | 241 | 61 | 25.31 | | |

Examined fish (EF), Parasited fish (PF), Prevalence (P).

*(Continued on next page)*

**Conclusion**

This study represents the first parasitological characterization of farmed tilapia in Angola, contributing significantly to the understanding of fish health in the country. The analysis of 241 clinically healthy specimens revealed an overall parasite prevalence of 25.3%, with the highest incidence of monogeneans (11.2%), followed by digeneans (9.5%) and nematodes (4.6%) found in external and internal organs.

The presence of multiple parasite groups across all production units evaluated suggests a widespread and cross-cutting dissemination of these agents in tilapia farming systems in the Huambo region. These findings underscore the urgent need to implement regular health monitoring and sanitary management measures to prevent outbreaks of parasitic diseases that could compromise animal welfare, productivity, and food safety.

# SPATIAL DISTRIBUTION OF CULTURED JUVENILES OF *Hediste diversicolor*

I. Martín*, S. Gago, M. A. Egea, D. Salazar, J. León and F. Aguado-Giménez

National Centre Spanish Institute of Oceanography (IEO-CSIC)
Planta de Cultivos Marinos 'EL Bocal'
Monte-Corbanera s/n, C.P. 39012, Cantabria
E-mail: nacho.martin@ieo.csic.es

**Summary**
The development of intensive cultivation of *H. diversicolor* requires the production of quality juveniles in adequate quantities for fattening. Considering the spontaneous and asynchronous reproduction of this species in captivity that produces successive batches of juveniles and the confinement of juvenile specimens in the top centimeters of the sediment, this experiment evaluates if the juvenile's distribution in the breeding tanks is homogeneous or it has a heterogeneous distribution with an aggregation pattern for application in the development of management protocols.

**Introduction**
The cultivation of polychaetes has been gaining interest due to their multiple applications; such as individual commercialization as bait for sport fishing, raw material for aquaculture feeds replacing fish oils and meals, or as direct food to stimulate reproduction in the shrimp farming industry, among others (Rasines et al. 2023). Under cultivation conditions, with sufficient food supply, *Hediste diversicolor* reproduces spontaneously and asynchronously, providing successive generations of juveniles. The juveniles are confined to the upper few centimeters of the sediment (Davey, 1994). Their distribution may affect the estimation of juvenile production and impact subsequent management, including the removal of juveniles from the breeding and independent fattening tanks. To advance the development of a fattening protocol for this species, this study analyzes the distribution of juveniles during three reproductive events in 1 m² cultivation tanks of *Hediste diversicolor* at the specific experimental polychaete cultivation research facilities (PAU) of the Spanish Institute of Oceanography-CSIC.

**Materials and Methods**
To estimate juvenile distribution, three 1 m² tanks were seeded with 20 cm of sand and approximately 15 cm of water column, using reproductive specimens cultivated at our facilities (P1 = 338 individuals, mean wet weight (MWW) = 1094 mg; P2 = 338 individuals, MWW = 1340 mg; and P3 = 300 individuals, MWW = 1024 mg). Cultivation was carried out in an open water circuit under natural temperature and salinity conditions, and photoperiod 16L:8D, feeding with commercial sole feed at a rate of 4% of the worm biomass per day, adjusting as needed to ensure availability.

One and a half months after seeding the breeders, a sampling was conducted to detect and quantify the juveniles produced. The sampling consisted of siphoning the top 2 cm of sand from alternating 10 x 10 cm quadrats, sampling every other square across the tank surface, resulting in 50 samples per tank. These sand and water samples were homogenized by gentle mixing, and three 5 ml subsamples were examined under a stereo microscope to identify juveniles of the species. The unsampled quadrats were estimated by calculating the mean number of juveniles in the adjacent sampled quadrats. The result was three 10 x 10 data matrices with values of juvenile identified per quadrat.

To assess the degree of homogeneity in the juvenile production tanks, Moran's I indices and associated p-values for each data matrix were calculated by permutations to evaluate the significance of the index. Additionally, coefficients of variation for each matrix were calculated.

**Results and Discussion**
A total of 20671, 13171, and 1208 juveniles were obtained in tanks P1, P2, and P3, respectively. The smallest juveniles detected had 8 setigerous segments, and the largest had 13. The distribution of juveniles identified in the subsamples and estimated in each tank is shown in figure 1.

Figure 1. Heatmap of observed and estimated juvenile distribution of *H. diversicolor* in 3 independent breeding tanks (P1, 2, and 3). The blue square represents the water inlet into the tank.

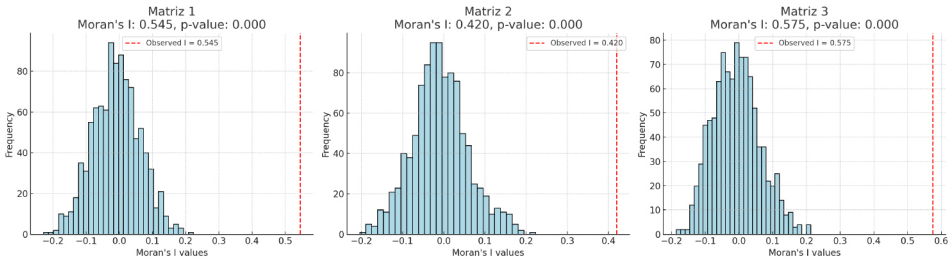

Figure 2. Results and graphical representation of Moran's index of spatial autocorrelation and associated p-value for each of the 3 data matrices of juveniles recorded in the 3 broodstock tanks.

The results showed Moran's I indices of 0.545, 0.420, and 0.575 for tanks P1, P2, and P3, respectively, with p-values of 0.000 in all cases (figure 2). Likewise, the coefficients of variation for the matrices were 49%, 56%, and 146% for P1, P2, and P3, respectively. Both results reflect the presence of strong positive spatial autocorrelations, with a tendency for clustering of cells with similar values, indicating a non-random pattern. Additionally, coefficients of variation close to or above 50% reflect high spatial heterogeneity. These results highlight the need to establish appropriate sampling techniques that adapt to the heterogeneous distribution of juveniles in the breeding tanks.

**Summary**
In this work, different wastes from agro-industries are evaluated from the point of view of growth performance and the resulting LC-PUFA composition in *Hediste diversicolor* as a preliminary step to the formulation of specific diets. Brewer spent grain, rosé wine lees and biofloc wastes were *a priori* selected on the basis of the growth performance and PUFA profile provided.

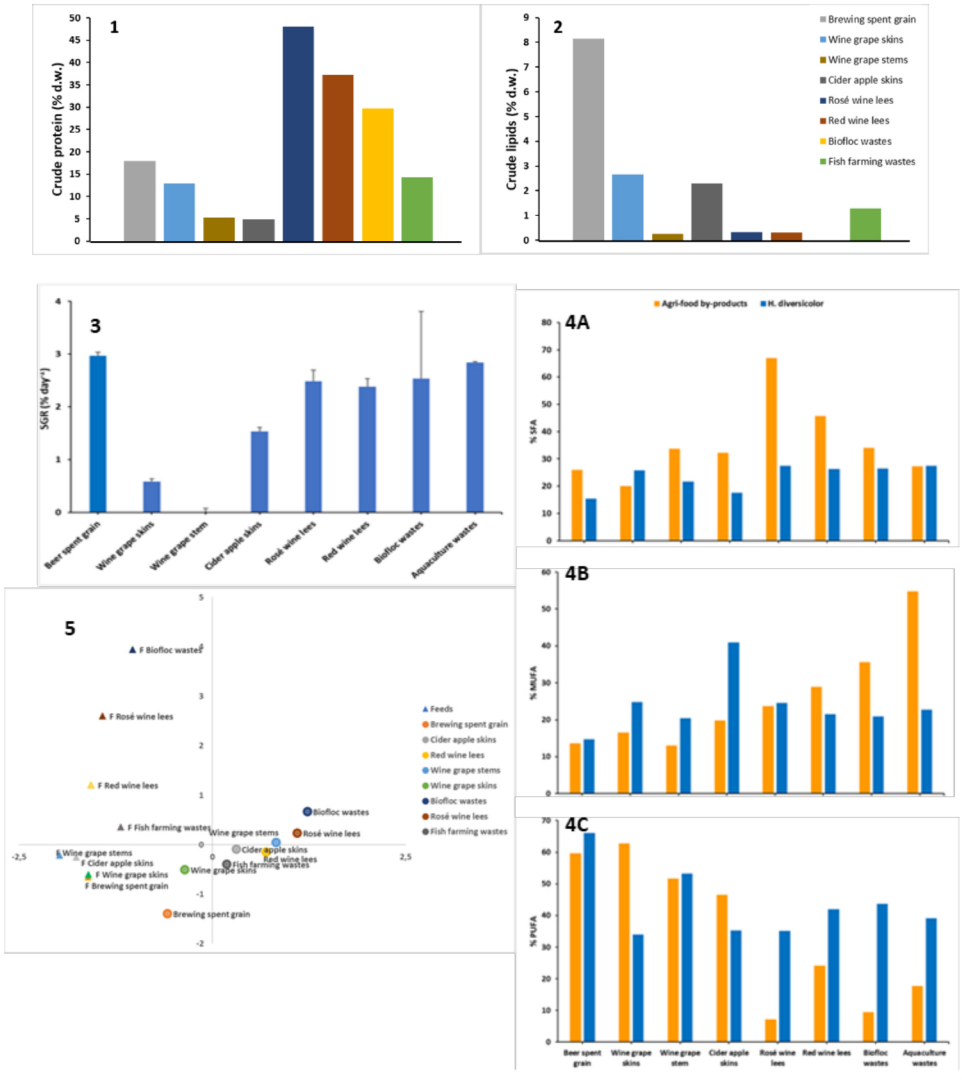
**Introduction**
The increasing interest in cultivation of the polychaete *Hediste divesicolor* is largely due to its ability to synthesise long-chain polyunsaturated fatty acids (LC-PUFA), particularly ARA and EPA, from lipid-poor substrates (Villena et al., 2025), giving it potential use as an alternative feed ingredient for fish and crustaceans. In order to achieve a production of *H. diversicolor* with an optimal nutritional composition, it is necessary to have a low-cost, high-performance feed. In the context of a circular economy, using low-lipid waste from the agri-food industry to produce a high nutritional quality product offers high levels of sustainability and business opportunity. In this work, several wastes from different agro-industries are evaluated from the point of view of growth performance and the resulting LC-PUFA composition in *Hediste diversicolor* as a preliminary step to the formulation of specific diets.

**Materials and Methods**
Eight agro-industry wastes were used to feed *H. diversicolor*, coming from brewing industry (brewing spent grain, BSW), wine industry (wine grape skins (WGSk) and stems (WGSt); rosé (ROWL) and red (REWL) wine lees); cider industry (cider apple skins, CAS) and aquaculture (biofloc wastes (BFW) and fish farming wastes (FFM)). The wastes were dried at low temperature (45 °C), grinded, and vacuum-packed for storage prior to supply. *H. diversicolor* juveniles taken form the stock of the Polychaete Aquaculture Unit (PAU) belonging to COST-IEO/CSIC with a mean body weight (BW) of 40.9 mg were placed in *ad hoc* experimental units (Aguado-Giménez et al., 2023) at a density of 1500 individuals $m^{-2}$ within a RAS system. Temperature was set to 18 °C, salinity was 35 ‰ and photoperiod was 14L:10D. Eight groups in triplicate were each fed one of the abovementioned feeds. Feed was provided *ad libitum* every two days for 3 months. At the end of the trial all specimens were (wet) weighed and specific growth rate ($SGR= (\ln BW_f - \ln BW_i)*100/ T_f-T_i$) was calculated. Protein, lipid and the fatty acid profile of all diets and of the resulting worms fed with such diets were analysed.

**Results and Discussion**
Figures 1 and 2 show the protein and lipid content in the raw materials tested. Figure 3 shows the mean SGR values for each diet. WGSk, WGSt, and CAS provided very low SGR results, and the other wastes gave similar SGR values between 2.5-3 % $day^{-1}$.

Figures 4A-C show the % of saturated (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) fatty acids of the diets and the resulting worms fed such diets, and Figure 5 shows the score plot of a Principal Components Analysis run with the fatty acid profiles of the diets and worms.

*(Continued on next page)*



*H. diversicolor* grew best with high-protein raw materials (BSG, ROWL, REWL, BFW and FFM). In addition, these worms transformed low-lipid raw materials with a high SFA and MUFA profile (ROWL, REWL and BFW) into PUFA-rich biomass. Considering the performance provided by the evaluated raw materials and their accessibility, we selected BSG, ROWL and BFW for feed formulation with different proportions of these raw materials (and others usually used in aquaculture feed formulation to enhance protein content) that are currently being tested in terms of growth and resulting lipid and free-AA profiles.

victoria.fernandez@ua.es

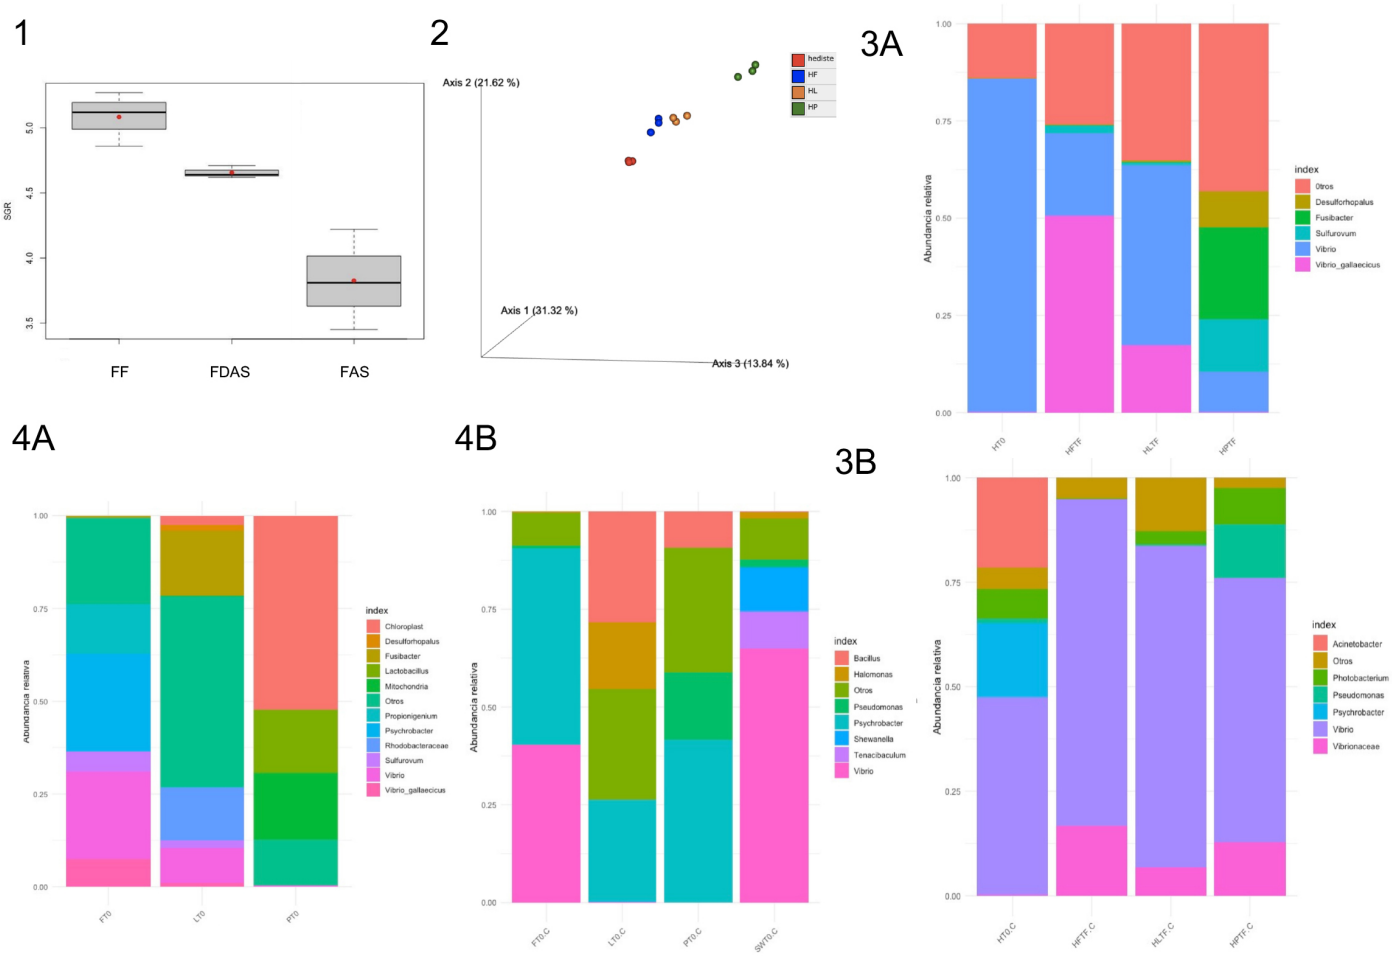
**Summary:**
The microbiota of *Hediste diversicolor* was studied under three diets: formulated fish feed (FF), fresh aquaculture sludge (FAS), and freeze-dried aquaculture sludge (FDAS). Growth was highest with FF. Microbial communities differed by diet: FAS and FDAS-fed worms were dominated by *Vibrio*, while in FF worms prevailed *Fusibacter* and *Sulfurovum*. Potential pathogens like *Vibrio harveyi* and *Photobacterium damselae* were found at low levels, mostly in both sludge-fed groups.

**Introduction:**
Integrated Multitrophic Aquaculture (IMTA) offers a sustainable model using polychaetes like *Hediste diversicolor* to convert organic waste into feed (Wang *et al*., 2019). Polychaete meals can replace fishmeal without harming fish growth, but EU rules limit use of potentially hazardous materials like fish feces. Assessing microbial risks is crucial, and 16S rRNA sequencing helps understand how diet affects *H. diversicolor* microbiota, in order to support its safe use in aquaculture (Austin and Austin., 2016).

**Material and Methods:**
This 46-day experiment involved 360 *Hediste diversicolor* juveniles reared in cylindrical experimental units within recirculating aquaculture systems under controlled conditions (18 °C, 35 PSU, 16L:8D). Three diets were tested: commercial fish feed (FF), and fish wastes (mix of faeces and uneaten feed) in two formats: fresh aquaculture sludge (FAS), and freeze-dried aquaculture sludge (FDAS), each with six replicates. Worm growth was measured every 15 days using specific growth rate (SGR). For microbiota analysis, DNA was extracted from whole worms, culturable bacteria grown on selective media, the diets, and seawater. The V3–V4 region of the 16S rRNA gene was sequenced via Illumina MiSeq and processed with QIIME2. Diversity indices (Shannon, OTU richness) and beta diversity (Weighted UniFrac) were calculated, and dominant taxa identified at phylum and genus levels. Potential pathogens were screened by BLASTn against SILVA references (≥ 98.7 % identity). Growth data were analyzed using repeated measures ANOVA in R.

**Results:**
The growth analysis of *H. diversicolor* revealed marked differences depending on the diet provided (Figure 1). Worms fed with FF showed enhanced growth compared to those fed with FAS and FDAS, suggesting a better nutritional suitability of natural substrates. Regarding the associated microbiota, principal coordinates analysis (PCoA, Figure 2) showed a clear separation between treatments. Worms fed with FF developed a microbial community that diverged more strongly from the initial state, while those fed with sludge maintained bacterial profiles closer to the original microbiota. Relative abundance bar graphs (Figures 3A-B) indicated that the genus *Vibrio* largely dominated the initial microbiota (~97%) and remained predominant in worms fed with FAS and FDAS. However, its presence decreased significantly in the FF-fed group (24%), allowing other genera such as *Fusibacter*, *Sulfurovum*, and *Desulforhopalus* to proliferate. In cultured samples, *Vibrio* was also the most abundant genus (47–78%), although it shared dominance with *Acinetobacter*, *Psychrobacter*, or *Pseudomonas*, depending on the diet. Finally, feed samples (Figure 4A-B) revealed that sludges contained bacterial genera also found in the worms, including *Vibrio*, *Psychrobacter*, and *Fusibacter*, as well as traces of plant-origin DNA. In culture media and seawater, *Vibrio* was also predominant, reinforcing its role as a central component of both the environmental and host-associated microbiota.

*(Continued on next page)*



*H. diversicolor* microbiota is dominated by Proteobacteria, mainly *Vibrio*. Diet impacts its composition: sludge-fed worms retain the original community, while pellet feed increases anaerobes like *Fusibacter*. No major human pathogens were found, but potential fish pathogens were present in worms and sludge, indicating possible transmission risks.

E-mail: felipe.aguado@ieo.csic.es

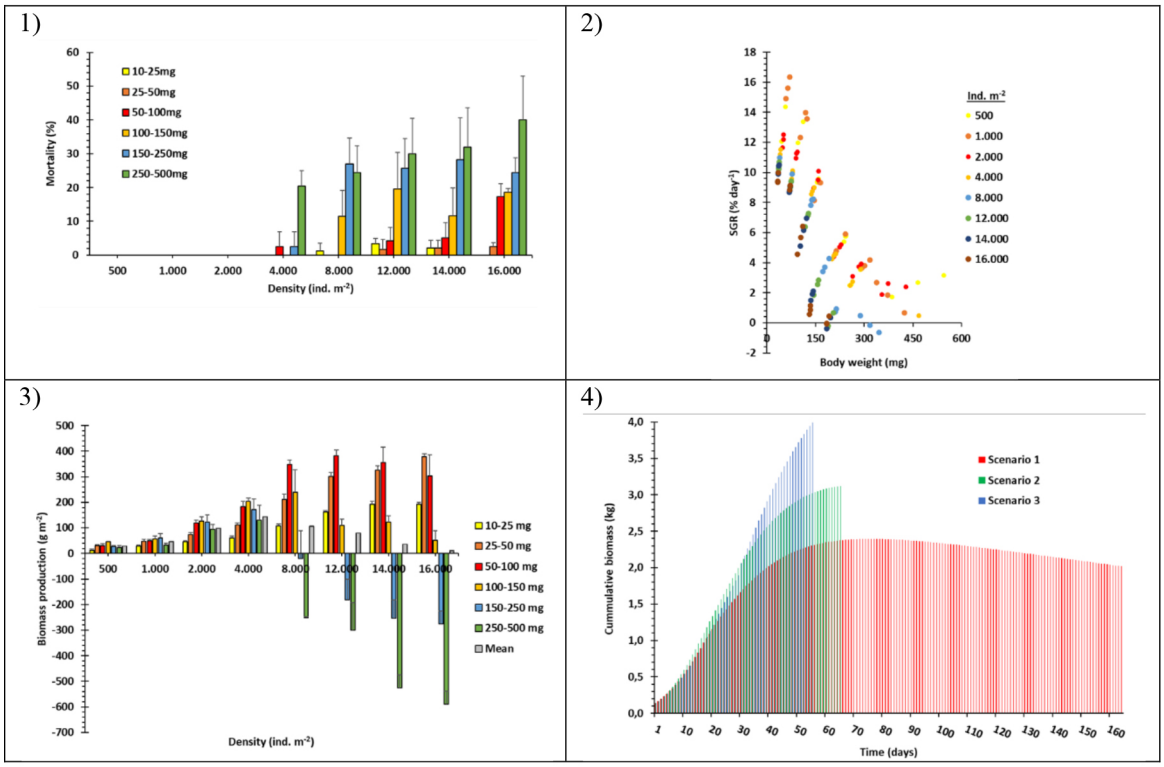
**Summary**
This study reveals the strong influence of density (D) on mortality (M), growth (SGR), feeding rate (SFR) and efficiency (FE) in *Hediste diversicolor*, as function of bdy weight (BW) and temperature (T). As D and BW increase M also increases but SGR decreases, but markedly from 8000 ind. $m^{-2}$. SFR and FE were also negatively correlated with D. SFR increased with T but FE decreased. Splitting during the fattening process leads to greater biomass production in a shorter time.

**Introduction**
Density is a determining factor in the structuring of benthic communities, particularly polychaetes. Under aquaculture conditions it is also of great importance for welfare, production performance and stock management. In this study we assess the influence of density on growth performance, feeding rate and efficiency in *Hediste diversicolor* of a wide range of body weight and temperature.

**Materials and Methods**
**Trial 1: Effect of individual size and density on growth**. Specimens of six different weight classes (10–25, 25–50, 50–100, 100–150, 150–250 and 250–500 mg fresh body weight (BW)) were placed in separate experimental units (EU) at eight different densities (D: 500, 1000, 2000, 4000, 8000, 12 000, 14 000 and 16 000 ind $m^{-2}$). All weight classes were represented in triplicate at the different densities in all trials. Worms were fed *ad libitum* with sole weaning pellets. After a period of 15 days, mortality (M: %), growth (SGR: % $d^{-1}$) and biomass production (BP: g $m^{-2}$) were calculated. Two-way ANOVA was used to check for the interaction effect of D x BW on M. Multiple regression analysis (MRA) is used to relate SGR to D and BW in order to obtain a predictive equation. Simulations are used to show production performance under different scenarios.

**Trial 2: Effect of individual size, water temperature and density on feeding rate (SFR) and feeding efficiency (FE)**. Specimens of six different weight classes (10–50, 50–100, 100–150, 150–200, 200–400 and >400 mg fresh BW) were placed in separate EUs at four different densities (D: 355, 1059, 1765 and 2471 ind $m^{-2}$) at three different temperatures (T: 14, 18 and 22°C). All weight classes were represented in triplicate in all trials at the different densities and temperatures. Before beginning the trials, the specimens in each EU were deprived of food for three days. Afterwards, they were fed daily at a high rate to ensure food was always in excess. The number of feed pellets (mean pellet weight previously measured) provided was pre-counted. At the start of each day, the EU surfaces were photographed under blue light, and leftover pellets were counted with ImageJ2 software. The number of pellets eaten the prior day was replaced to maintain continuous access to feed. This routine continued for four days, after which the animals were weighed and returned to their EUs. The entire process—three days of fasting and four days of feeding—was then repeated once. SFR and FE was calculated according to feed intake. The three-day fasting period between feeding tests ensured that all specimens would begin the next feeding trial with similar hunger levels, preventing repeated measure bias. Multiple regression analysis is used to relate SFR and FE data to D, T and BW

*(Continued on next page)*



**Results and Discussion**

D x BW interaction on M was significant ($P < 0.001$), so that the higher the D and BW, the higher the M. From a D of 8000 ind. $m^{-2}$ and a BW greater than 150 mg, the observed M is nearly 40%. (Figure 1). MRA revealed a significant and negative interaction of D x BW on SGR (SGR = 33.89 - 5.08·Ln(BW) - 8.52·10-5·D·Ln(BW); $R^2$ adj.: 0.79; $P < 0.0001$). As BW and D are low, SGR tends to be higher, and the opposite is also true. Once D exceeds 8,000 ind. $m^{-2}$ and BW is above 180 mg, SGR turns negative: as density increases further, growth becomes even more negative (Figure 2). BP increases as density and weight increase, but above 8000 ind. $m^{-2}$, low growth and mortality do not compensate the BP for BW > 150 mg (Figure 3). Simulations for BP were performed under different scenarios: SC1) initial D of 8000 ind $m^{-2}$ without any population split; SC2) initial D of 4000 ind $m^{-2}$ without any population split; SC3) initial seeding at a D of 8000 ind $m^{-2}$, with a first splitting at a D of 4000 ind $m^{-2}$ when worms reach a mean BW of 150 mg and a second splitting at a D of 2000 ind $m^{-2}$ when reaching a mean BW of 250 mg. Simulations revealed that splitting allows to obtain larger BP in a shorter time (Figure 4).

Similarly, MRA revealed that as BW and D decreased, SFR and FE increased: Ln(SFR) = 2.77 – 0.31·Ln(Bw) + 0.91·Ln(T)-0.34·Ln (D) + 5.4· 10-5·D·Ln(Bw); ($R^2$adj = 0.54; $P < 0.0001$ Ln(FE) = 10.02 – 5.1·10-4·Bw -0.02·T – 0.82·Ln(D) - 3.5·10-5·D·Ln(Bw); $R^2$adj = 0.81; $P < 0.0001$. With regard to temperature, as it increases, the SFR also increases but the FE decreases.

Density significantly affects *Hediste diversicolor* development, with small individuals (<150 mg) exhibiting rapid growth even at high densities, while larger specimens experience reduced growth and survival at increased densities. Adjusting densities through splitting as the worms grow shortens production cycles and minimizes mortality but increases space requirements. Feeding rate and efficiency are also strongly impacted by density, temperature, and body weight.

Trial 2 is part of the POLYPUFA project (PID2022-136234OB-C22) funded by the Spanish Ministry of Science and Innovation and Universities (MCIN/AEI/10.13039/501100011033).

# OFFSHORE LOW-TROPHIC AQUACULTURE MULTI-USE REALISATION (OLAMUR): PRODUCTION POTENTIAL AND ECOSYSTEM SERVICES OF LOW TROPHIC AQUACULTURE AT MULTI-USE AREAS IN THE BALTIC AND NORTH SEAS

Antonio Agüera*, Marie Maar, Charlotte H. Clubley, Jonne Kotta, Johannes Pein, Joanna Staneva, Annette Bruhn, Bela H. Buck, Wolf Isbert, Marianne Thomsen, Jun She, Dorothy Dankel, Giulia Dapueto, Antonio Novellino, Georg Martin, Øivind Bergh

Nordnes, 5817 Bergen Norway
antonio.aguera@hi.no

The recent expansion of offshore wind power has emphasized conflicts among different stakeholders. This need for more efficient use of marine area has highlighted the potential for multi-use, i.e. the use of area for more than one purpose. Aquaculture of low-trophic species (LT) (non-fed aquaculture) appears as an attractive way to increase sustainable biomass production. Additionally, LT species such as bivalves or seaweeds provided diverse ecosystem services such as the removal of nutrients or water clarity. Thereby, LTA can improve water quality and deliver ecosystem services, while contributing to the circular bioeconomy. As such activities may be combined in the same area, there has been considerable interest in developing multi-use systems for both industries, contributing to a range of UN Sustainable Development Goals (SDGs).

In the OLAMUR project, we are developing initiatives for multi-use involving low-trophic aquaculture (LTA) in the Baltic and North Seas. with offshore wind, combined with cultivation of mussels and seaweeds. The Baltic case is situated at Kriegers Flak, in the Danish sector, and the North Sea case is north of the island of Helgoland in the German sector. At both sites, large scale offshore wind farms have been developed and are now in the production phase. The Baltic case started seaweed cultivation in 2023, and mussel cultivation in 2024, and the German case starts in 2024. A third multi-use case study, in Estonian waters, combines cultivation of seaweeds and mussels with rainbow trout farming.

Among other specific objectives, OLAMUR aims to assess the suitability of the production of LT species in the multi-purpose use locations assessing the production potential and the efficiency of co-use scaled farming scenarios (OWF and IMTA) represented by the 3 established pilots. OLAMUR uses state-of-the-art ecological modelling approaches coupled with Dynamic Energy Budget Individual Based population models (DEB-IBM) for mussels, seaweed and fish. These models are validated through the data gathered at the pilots and are used to assess the farm-scale spatial production patterns and potentials for providing ecosystem services (uptake of nutrients). The models link local environmental conditions with the physiological performance of the crop to allow estimations of spatial and temporal variability of the crop status and are used to compare the different pilots, different farming scenarios and the development of tools for site selection.

OLAMUR runs a databased service system to assist policymakers in making knowledge based decisions, and an extensive Data Management Plan ensures transparent and standardized data capture from all parts of the project.

# GENOMIC ADAPTATIONS OF *Litopenaeus vannamei* IN AN INDOOR BIOFLOC AQUACULTURE SYSTEM

Edward T. Akange*[1,2], Olumide A. Odeyemi[3], Victor T. Okomoda[4] and Nor A. Kasan[1]

**Introduction**
Biofloc technology (BFT) enhances water quality, nutrient recycling, and disease resistance in shrimp aquaculture through microbial activity. This study investigates the gene expression responses of Pacific whiteleg shrimp, *Litopenaeus vannamei*, to varying biofloc conditions in an indoor system. This research focuses on molecular adaptations essential for shrimp health and sustainable production.

**Materials and Methods**
Tissue samples from *L. vannamei* were collected from three treatments (GRG 1: 200 shrimp/$m^3$, C/N ratio 10, 14 ml/L probiotic; GRG 2; Control), each with three replicates. RNA was extracted following the methods described in Masoodi et al. (2020), treated with DNase, and quality-checked (260/280 ratio: 1.9–2.1). mRNA was purified, fragmented, and converted to cDNA. Libraries were sequenced on an Illumina platform, with raw reads filtered using FastQC, MultiQC, and Cutadapt. Clean reads (>97%) were aligned using HISAT2, and differentially expressed genes (DEGs) were identified via DESeq2 ($|\log_2(\text{FoldChange})| \geq 1$, padj $\leq 0.05$). Functional enrichment used ClusterProfiler with KEGG annotation to indicate the pathways of biological significance in each set of DEGs.

**Results**
Gene expression analysis identified substantial DEGs: 1245 in GRG 1 vs. Control; 1145 in GRG 2 vs. Control; and 681 in GRG 1 vs. GRG 2 (Figure 1). Figure 2 also indicated distinct DEGs in the biofloc treatments relative to control. GRG 1 vs. Control showed upregulated proteasome (Rpn5, β4), autophagy (LC3 up 5-fold), and phagosome (Tubulin α up 10-fold) pathways. GRG 2 vs. Control showed increased level of aminoacyl-tRNA biosynthesis (alanyl-tRNA synthetase) and endoplasmic reticulum protein processing (SEC23/24 up 5-fold).

**Discussion**
GRG 1 biofloc conditions significantly enhanced shrimp physiology. The proteasome pathway showed upregulated subunits (Rpn5, β4) indicating an improvement in protein degradation and cellular homeostasis as earlier reported by Said *et al*., (2022). Autophagy pathways showed upregulation (4–5-fold) of LC3 and TSC1 to represent enhanced stress resilience as shown in earlier studies by Broadbent et al., 2023). Phagosome pathways showed upregulation (5–10-fold) for Tubulin α and integrin suggesting a boost in immune responses empirically verified by Mao *et al*., (2020). Upregulation of Alanyl-tRNA synthetase in Aminoacyl-tRNA biosynthesis pathway of GRG 2 supported protein synthesis. Endoplasmic reticulum protein processing enhanced protein trafficking with the upregulation of SEC23/24 and Hsp70 earlier confirmed by Belenichev *et al*., (2023).

**Conclusion**
The significant upregulation favouring GRG 1 biofloc treatment for proteasome, autophagy, and phagosome pathways in *L. vannamei* confirmed improved stress management and immunity. GRG 2 on the other hand supports protein synthesis and trafficking. These genomic insights confirm the role of BFT in improving shrimp health and advancing sustainable aquaculture.

# INVASION OF THE BLUE CRAB (*Callinectes sapidus*) IN ITALIAN WATERS: A REVIEW OF CURRENT KNOWLEDGE, IMPACTS, AND MANAGEMENT GAPS

Kazi Rabeya Akther[1,2*], Benedetto Sicuro[1], Maurizio Pinna[2]

[1] Department of Veterinary Sciences, University of Torino, Turin – Italy
[2]Department of Biological and Environmental Sciences and Technologies, DiSTeBA, University of Salento, Via Monteroni 165, 73100 Lecce, Italy
*Email: kazirabeyaakther@gmail.com

The blue crab (*Callinectes sapidus*), a species native to the western Atlantic, has become an aggressive marine invader in the Mediterranean, with Italy experiencing particularly severe ecological and economic consequences. This review synthesizes recent literature (2010–2024), gray reports, and unpublished data on the distribution, biology, ecological impact, and management responses to the species' spread along Italian coasts, especially in the northern Adriatic, central Tyrrhenian, and Sicilian lagoons. Key studies report rapid population increases, with reproductive females and juveniles found throughout most surveyed lagoons. Reviewed methodologies include baited trap surveys, remote sensing for habitat mapping, stable isotope analysis, and socioeconomic assessments via fisher interviews. Impacts identified include predation on native bivalves (e.g., *Ruditapes philippinarum*), competition with native crustaceans, and disruption of aquaculture and artisanal fisheries. While several regional mitigation strategies such as population control through targeted fishing have been trialed, a coordinated national response is lacking. Notably, there is minimal integration of ecological data into policy, limited market development for blue crab as a fishery resource, and inadequate long-term monitoring programs. This review highlights the urgent need for multidisciplinary research and management approaches that address both ecological and socioeconomic dimensions of the invasion. Critical gaps remain in understanding larval dispersal mechanisms, overwintering survival, and adaptive ecosystem responses, which are essential for predicting future expansion and informing policy.

# OCEAN FISH FARMING – ENSURE SAFE AND SUSTAINABLE OPERATIONS

Mr. Aland, PA

DNV – Det Norske Veritas
Veritasveien 1
1363 Høvik, NORWAY
e-mail: per.arild.aland@dnv.com

## INTRODUCTION

Oceans space offers a vast opportunity to meet marine protein demand with sustainable, safe and efficient fish farming, but how do we maintain safety of facility, personnel on board and prevent fish escape together with maintaining fish welfare and reducing emissions to marine environment. Adding safety to fish farming operations is mainly ensured by providing uniformity, transparency, and predictability and thereby securing the total safety performance. This paper reflects and address overall risk perspectives combined with applicable taxonomy of essential items crucial for maintaining safe aquaculture operations in ocean space.

## MAIN APPROACH

The main areas of concern when it comes to ensuring safe and reliable fish farming units may be categories into: Integrity of facility, personnel safety, fish welfare, maintaining ocean health and prevention of fish escape. An integrated risk methodology based on these four items results in a cost-efficient approach to reduce operational risk and establish sufficient safety level.

### Integrity of facility

Integrity of facility includes structural strength, stability, mooring, technical arrangement, and solutions on board together with reliability of essential equipment installed. Integrity of vessel or installation itself is directly relevant to existing scheme for qualification or classification. Experience from more than 50 years of design and operation of complex steel structures in demanding marine environment are compiled in the classification rules. This maritime execution model has been applied in the six first fish farming installations put into operation in Europe.

### Personnel safety

Personnel safety is mainly addressing arrangement for emergency escape and fire safety. Maintaining Health, Safety and Environment for personnel working on board a fish farming installation is demanding since challenging task are performed daily in hash, marine environment. Special considerations need to be taken due to offshore/maritime operational mode. This included lifesaving appliances, launching equipment and similar as well as fire detection and -extinguishing. It is common to apply well know maritime IMO-codes as acceptance criteria for personnel safety. These codes also describe certification process and how to prototype test to ensure reliable safety equipment on board. SOLAS is a good example followed by local flag- or shelf states interpretation of requirements embedded in this maritime code.

### Fish welfare

Fish welfare and requirements related to this varies depending on local authorities. It is essential to verify the reliability of technology utilized to monitor environment of the fish. Instrumentation indicating oxygen level, temperature, salinity, turbidity is subject for special attention. Maximum acceptable level of biomass is also a crucial parameter that needs to be monitored.

In general capability and reliability of the equipment and systems on the installation that affects welfare, health and physical condition of finfish need to be addressed systematically. As a result, items for fish welfare on board such as cleaning, exposure to chemicals, medication, crowding, fish transfer and monitoring of health condition are of the essence.

### Ocean health

A significant risk in ocean aquaculture is substandard sustainability due to emissions from fish farming installation. It is considered essential to monitor and limit pollution from e.g. fish waste, feed surplus, chemical substances from net cleaning and emissions from medical treatment of feed stock. This to ensure that environmental impact of fish farming operation does not exceed the sustainability limits of marine environment. Sustainable aqua operation is mainly achieved through monitoring performance and ensuring that biodiversity targets for marine environment are reached.

*(Continued on next page)*

**Fish escape prevention**
Fish control or prevention of escape is the main function of a fish farming unit. Structural integrity of net system and ropes together with capability of fish transfer systems are crucial items in fish control. Flexible net systems utilized in rigid high volume steel fish farming installation has proven to be exposed to fatigue and need to be attended to in particular. Wear and tear of net due to cleaning and handling is also a concern. Several of reported incidents related to fish escape happens while handling of fish – for example crowding due to de-licing or transfer. Equipment contributing to these operations needs to be specially attended to.

In addition to arrangement representing physical barriers preventing the fish to escape, all other systems and components that may cause fish escape if they fail or malfunction in any way need to be certified.

The four different items listed above, asset integrity, personnel safety, fish welfare and fish control, are considered equally important for safe and sustainable fish farming offshore. These elements are also closely interconnected where integrity of one may support several others.

**CONCLUSION**
There is a significant potential to utilize competence from traditional offshore and maritime industry to help operators of exposed fish farming units to identify operational risks by applying technical rules and requirements from traditional maritime execution model.

Combining the well-known certification concept from maritime industry with balanced aquaculture-based requirements for fish welfare and biodiversity provides a robust and cost-efficient solutions to reducing risk in operation of ocean fish farming installations.

# GLOBAL OCEAN HEALTH STANDARD - SUPPORTING SUSTAINABILITY IN AQUACULTURE

Mr. Aland, PA

DNV – Det Norske Veritas
Veritasveien 1
1363 Høvik, NORWAY
e-mail: per.arild.aland@dnv.com

## INTRODUCTION

Marine aquaculture has grown into a vital industry, providing an alternative source of seafood while supporting the global animal-source protein supply worldwide. However, with this rapid expansion comes a pressing need for consistent regulations, improved aquaculture facilities, and sustainable operations to ensure long-term viability.

A global ocean health standard focusing on controlling and reducing emission from aquaculture activity to marine environment is one of many initiates to improve sustainability in global aqua-industry.

## MAIN APPROACH

An ocean health standard is established and serves as a key framework for certifying and improving sustainability, and establishes best practices for designing, constructing, and maintaining aquaculture facilities to ensure environmentally responsible operations. It outlines comprehensive measures to ensure the health and welfare of farmed fish stocks while limiting the overall environmental impact from aquaculture operations. Some of the key drivers to implement requirements in this standard include:

- Sustainability & environmental responsibility: Strategies to mitigate the impact of fish farming on surrounding ecosystems, including waste management and water quality control.
- Operational efficiency & cost optimization: Guidelines for optimizing farming operations to maximize productivity while maintaining sustainable practices.
- Market competitiveness & business growth: Certification with focus on monitoring and limiting discharge from aquaculture operations, helping fish farmers differentiate themselves in the rapidly emerging and competitive aquaculture markets, through improved sustainability, operational efficiency, transparency, and operative predictability.

By adopting to these requirements, fish farming companies may potentially improve consumer trust by increased sustainability through enhanced operational performance and reduced environmental impact. This is mainly achieved through limiting the discharge to the marine environment from aquaculture operations.

As global seafood demand rises, sustainability has become an essential aspect in current aquaculture. Poorly managed fish farms can cause significant negative environmental impacts related to e.g. spread of infectious agents, fish escape as well as nutrient- and chemical discharge, leading to water pollution, destruction of marine ecosystems and biodiversity loss. Therefore, we see that fish farming industry is rapidly developing innovative solutions to face these challenges.

This ocean health standard addresses marine environmental concerns by requiring a site-specific biosecurity plan for each production cycle, with special attention to local conditions. Additionally, it mandates a baseline survey of the installation- and transition zones before aquaculture facility is installed, and/or before substantial expansion. This provides a benchmark to measure changes over time, allowing for the detection of trends and shifts in environmental conditions. Furthermore, this set of requirements also encourages improved waste management through the implementation of a waste plan for waste storage and treatment for sewage and solid waste together with sludge collection. These measures illustrate some examples of how the standard ensures that fish farms contribute to cleaner water and healthier aquatic habitats.

## CONCLUSION

The aquaculture industry faces increasing demands for food security, environmental responsibility, and technological advancement. As we move forward, continued innovation and adherence to best practices will be essential to maximize the potential of fish farming and ensure its role as a sustainable source of seafood. Compliance with consistent requirements such as the standard DNV-ST-0678 “Environmental impact of marine aquaculture installations” will be necessary for the aquaculture sector to achieve long-term success. Ultimately, this standard serves as a roadmap for responsible, high-performance aquaculture that can meet the challenges of the next decade and beyond.

# STRESS-INDUCED DISRUPTION OF CIRCADIAN SEROTONIN SYNTHESIS IN THE GUT OF RAINBOW TROUT (*Oncorhynchus mykiss*): EXPLORING L-TRYPTOPHAN AS A PREVENTIVE STRATEGY

M. Alborja-Valado[1]; A. Verde[1]; C. Ramírez-Rodríguez[1]; M. Chivite[1]; J. Calo[1]; M.A. López-Patiño[1]; J.M. Miguez[1]

Email: maria.alborja@uvigo.es

**Introduction**

Welfare is critical in aquaculture, especially when considering that farmed fish can experience stress. Stress negatively affects a wide range of physiological and behavioural functions, including disruption of rhythmic processes that are largely dependent on the circadian system. The gastrointestinal tract (GIT) plays a critical role in nutrient absorption and energy homeostasis, and its regulation involves multiple neuroendocrine processes. Several monoamines display an important role in gut, with special relevance of serotonin (5HT). In fish, this monoamine participates in the modulation of feeding behaviour, but also in the physiological stress response. In addition, 5-HT specifically regulates several functions within the GIT, such as motility, secretion, and daily rhythms through specific receptors. Its synthesis takes place from the essential amino acid L-tryptophan (L-Trp), whose role in contributing to animal welfare is expected. Dietary supplementation with L-Trp appears to suppress aggressive behaviour and reduce circulating cortisol after acute stress in some teleost species (Höglund *et al*., 2019), limiting its synthesis and release in long-term trials (Herrera *et al*., 2019). In addition, L-Trp promotes synthesis of intestinal melatonin, which may influence the circadian regulation and the physiological response to stress (Acharyya *et al*., 2021). However, the benefits of L-Trp are not demonstrated at all, and it has been also reported to enhance plasma cortisol levels in rainbow trout (Lepage *et al*., 2002), thus negatively affecting different regulatory systems, such as the serotonergic system, which is involved in GIT immune function (Machado *et al.*, 2019). Then, there is a need to deep into the understanding of the mechanisms involving L-Trp in GIT, and to corroborate if dietary supplementation with the amino acid is effective on preventing the adverse effects of stress in farmed fish.

Therefore, this study aimed to evaluate how prolonged crowding stress affects the gastrointestinal serotonergic system in rainbow trout, and the potential benefits of dietary supplementation with L-Trp on protecting serotonergic activity from stress.

**Materials and Methods**

Immature rainbow trout (*Oncorhynchus mykiss*) were obtained from a local fish farm and kept at the University of Vigo. Fish were acclimated to a 12L:12D photoperiod, with daily feeding at ZT3 (ZT0 = lights on), and then divided into four groups regarding the stress and feeding paradigms: 1) Control (no stress) fed with control feed (0.2% L-Trp) (CC); 2) Control fed supplemented feed (1% L-Trp) (TC); 3) Stress fed with control feed (CS); 4) Stress fed with supplemented feed (TS). Supplementation of the diet with L-Trp began 7 days prior to the stress by overcrowding being applied. To stress the fish, the volume of water in the tanks was reduced to reach a high stocking density (70 Kg of fish/100 L) and remained up to 96 hours. Non-stressed trout remained in normal stocking density (10 Kg/100 L). On the day of sacrifice, groups of fish were euthanized every 4 hours throughout the following 24 h (ZT0, 4, 8, 12, 16, 20, and 0'), and individual samples of blood and foregut were collected. Plasma obtained from the blood samples was assessed for cortisol levels by EIA. The samples of foregut were used to quantify 5-HT levels by HPLC, as well as the relative mRNA abundance of tryptophan hydroxylase (*tph1*, *tph2*), the rate-limiting enzyme in serotonin, by qPCR. Significant differences between the experimental groups were determined using ANOVA and post hoc multiple comparisons test. In addition, the consistency of the daily rhythms of each parameter and their characteristics were evaluated by the COSINOR analysis.

*(Continued on next page)*

**Results and discussion**

In non-stressed group, a daily rhythm of cortisol levels was observed, with the acrophase (time of the peak) located at the end of the night. In fish fed with regular feed and subjected to overcrowding (CS group), the acrophase shifted and relocated in antiphase (ZT10.53) with that of control group. The amplitude of the rhythm raised up to 50 % and the mesor duplicated. In stressed trout fed with L-Trp supplemented feed (TS), the rhythm was not consistent due to decreased amplitude, but the profile paralleled that of the control group. The rhythm of cortisol in non-stressed group fed with the L-trp supplemented diet (TC) remained, with slight changes consisting of a nearly 3-hours shift of the acrophase, and a slight increase of amplitude and mesor. With respect to cortisol, non-stressed fish showed lower mean daily levels than those fish subjected to stress. In addition, the group receiving L-Trp (TC) showed slightly higher values than the control. Concerning 5-HT levels in the foregut, a significant daily rhythm was denoted in the control group (CC) with the acrophase occurring at ZT10.73. Under stress conditions (CS), the rhythm was not consistent, but the profile was similar to that of control. L-Trp was partially effective in preventing the effect of stress on the rhythm of 5-HT (TS group), although the acrophase changed. Non-stressed trout fed with supplemented feed (TC) preserved the daily rhythm of 5-HT, but the acrophase was in antiphase with respect to that of control group. Finally, with respect to *tphs* mRNA abundance, daily rhythms occurred in control group. Stress inhibited the expression of both *tph1* and *tph2*, and L-Trp supplementation was effective on preventing the effect of stress, even when slight variations on the acrophase occurred when compared to control group.

Taken together, our results suggest that L-Trp may protect the serotonergic system from tress, thus suggesting a potential use as preventive strategy in the aquaculture context, when stressful manipulations are expected.

**Introduction**

Edible algae are gaining importance in sustainable agri-food systems, with over 20 species recently authorised as novel foods in Europe[1]. However, their microbiological safety poses some concerns due to sporadic outbreaks linked to pathogenic bacteria and enteric virus contamination. This study investigates the identification of the microbial risks associated with edible algae and the implementation of cold plasma (CP) treatments, as a promising technology effective in preventing and controlling foodborne diseases.

**Material & Methods**

First, the microbiological analysis of diverse species of edible algae, either fresh and dried, was carried out for mesophilic aerobic bacteria (ISO 4833-1:2003), yeasts and moulds (ISO 21527-1:2008), *Enterobacteriaceae* (ISO 21528-2:2017), *Escherichia coli* (ISO 16649-2:2001), *Listeria* spp. (ISO 11290-2:2017), *Salmonella* spp. (ISO 6579-1:2017), *Vibrio* spp. (ISO 21872-1:2017), and *Clostridium* spp. (ISO 15213-2:2023). As well, enteric viruses were targeted according to the BAM FDA method for GI and GII human noroviruses (HuNoV), hepatitis A virus, astrovirus, human sapovirus (HuSaV), rotavirus, and mengovirus, as a process control. The efficacy of CP treatments generated by a dielectric barrier discharge (DBD) device was then evaluated for the inactivation of selected foodborne pathogens under varying operating conditions (e.g., exposure time, power, and gas composition) in algae. The efficacy of the treatment was assessed by plate count for *Listeria monocytogenes* and replication in cell culture for viruses, including murine norovirus (MNV) as cultivable surrogate.

**Results**

The microbiological analysis showed the presence of aerobic mesophilic bacteria (6.84 log CFU/g), moulds and yeasts (5.48 log CFU/g) in all fresh and dried algae samples. Potential foodborne pathogens, such as *Enterobacteriaceae*, *E. coli*, *Listeria* spp., *Salmonella* spp., and *Vibrio* spp., were detected in both fresh and dried algae, with presence varying depending on the sample. Dried algae were found to be contaminated with *Clostridium* spp (Fig. 1). Non-quantifiable HuNoV GII was detected in all fresh and dried *Ulva lactuca* samples (Fig. 1).

CP with $O_2$ resulted in a time- and power-dependent *Listeria monocytogenes* reduction in algae (Fig. 2A), reaching complete inactivation after 30 minutes at 300 W. CP with $N_2$ at 300 W resulted in the best operative conditions for MNV inactivation (>4 log, Fig. 2B), while $O_2$ completely inhibited HuNoV II replication after 20 min (4.9 log, Fig. 2C). CP at 300 W determined HuSaV complete inactivation after 20 min irrespective of the gas composition (2.5 log, Fig. 2D).

**Discussion**

This study showed bacterial and viral contamination in both fresh and dried algae, which levels are consistent with previous reports for marine products[2, 3]. The presence of *Enterobacteriaceae* and HuNoV suggests that faecal contamination occurs in both indoor and outdoor cultivation systems. Also, *Vibrio* spp. detection raises concerns as one of the zoonotic agents to be mandatorily monitored in sea products (2003/99/EC). Given such contamination, CP was hypothesized as an effective no-thermal decontamination technology for pathogen control in algae[4, 5]. Non-thermal treatments such as UVC light and gamma radiation have been shown to reduce hepatitis A virus and murine norovirus viral loads by up to 3 log in various edible seaweeds, without affecting their sensory quality[6, 7]. Cold plasma has proven effective for viral inactivation, reducing 4.22 log of MNV on raspberries after 5 minutes, and >5 log on blueberries after 1.5 minutes[8, 9]. Testing the combination of different operating conditions, our results demonstrated the complete inactivation of human bacterial and viral foodborne pathogens after 20-30 min exposure at 300 W with $O_2$. These advances serve to consolidate CP as an innovative alternative for improving the microbiological safety of novel food products such as edible algae.

*(Continued on next page)*

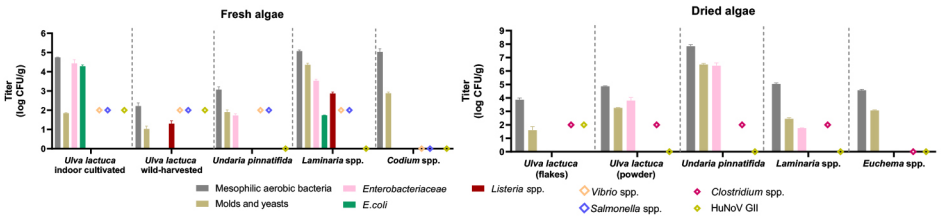

**Figure 1**. Foodborne bacterial and viral pathogens in fresh and dried edible algae. Bars represent quantifiable determinations (mean ± SE), while diamonds represent unquantifiable determinations (presence/absence).

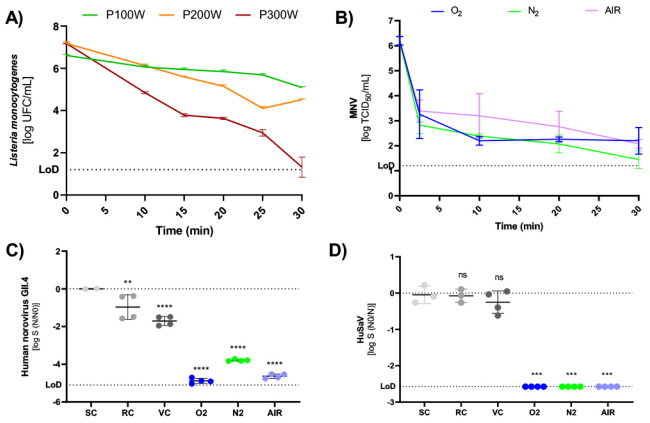

**Figure 2**. Assessment of the inactivation kinetics of CP treatments for *Listera monocytogens* (panel A) and MNV (B), and validation against HuNoV (C) and HuSaV (D) in contaminated kombu. Operating conditions included exposure time, power (100, 200, and 300 W), and gas composition (oxygen, $O_2$; nitrogen, $N_2$; or air, AIR). Experiments included solution (SC), recovery (RC), and vacuum (VC) controls.

## Conclusion

The study reports bacterial and viral pathogen contamination on edible algae, raising concerns about the microbiological risk for consumers. To guarantee food safety, cold plasma was demonstrated as an effective technology for pathogen inactivation at specific operating conditions. Overall, these results support the cold plasma technology for enhancing the food safety of marine products.

# PHYSIOLOGICAL RESPONSES OF *Pinna rudis* TO DIFFERENT EXPERIMENTAL DIETS: A STEP TOWARD CAPTIVE CULTURE OF *Pinna nobilis*

Rosa Alcaraz*[1], Sebastián Hernandis[1], José Francisco Sánchez de Prado[2], Silvia Sanchez-Segarra[1], Elena Chaves-Pozo[1], José María García-Beltrán[1], Maite Vázquez-Luis[3], José Rafa García-March[2] and Marina Albentosa[1]

## Introduction

In recent years, *Pinna nobilis*, an endemic species of the Mediterranean Sea with high ecological value, has suffered mass mortality mainly due to the protozoan *Haplosporidium pinnae*, in combination with other pathogens (Carella et al., 2023). The species is currently critically endangered, with remanent populations restricted to a few protected coastal environments such as lagoons and estuaries (sanctuary areas), where salinity conditions appear to limit the progression of the disease (Katsanevakis et al., 2022). However, even these remaining populations are showing alarming declines in individual numbers and absence of recruitment (García-March et al., 2019; Nebot-Colomer et al., 2024).

Given this situation, the development of captive breeding protocols is considered a key tool for the conservation of the species. Nevertheless, all attempts made so far have failed to maintain *P. nobilis* specimens in good physiological condition over the long term or to induce successful reproduction (Hernandis et al., 2023). Among the main limiting factors in this context, diet—both in quantity and quality—plays a critical role. In particular, the type of diet provided can significantly affect the nutritional and physiological status of filter-feeding bivalves.

With the aim of improve the feeding strategies for captive culture, an experiment was conducted with juveniles of *Pinna rudis*, a protected species phylogenetically close to *P. nobilis*, to evaluate the physiological and growth responses of *P. rudis* to different experimental diets. This approach represents a necessary step toward the implementation of aquaculture-based strategies for the recovery of *P. nobilis*.

## Material and methods

Juveniles of *Pinna rudis* (11–55 mm) fixed to the ropes of fish aquaculture farms (Villajoyosa, SE, Spain) were obtained and acclimated for two weeks in open-flow aquaria under controlled salinity (37 – 38 PSU). During acclimation, individuals were fed a control diet of *Tisochrysis lutea* and *Chaetoceros neogracilis*, the FAO-recommended microalgae mix for bivalve culture. The experimental system consisted of five flow-through chamber (FTC) units (8 chambers each), with 7 chambers per unit housing two individuals each, and 1 blank chamber without animals. All experimental diets consisted on the microalgae FAO-mix, in which one portion was replaced by the following microalgae: (1) control diet (FAO-mix without replacement, C), (2) carbohydrate-rich (with *Rhodomonas lens*, RL), (3) eicosapentaeinoic acid (EPA)-rich (with *Tetraselmis suecica*, TS), (4) lipid-rich (with *Diacronema lutheri,* DL), and (5) high in inorganic matter (with added kaolin, K). Antibacterial activity was tested on each microalgae by measuring the inhibition of growth of fish pathogenic bacteria *Vibrio harveyi* (Vh) as previously described (García Beltrán et al. 2018). After one month under experimental conditions, physiological measurements were conducted, including clearance rate, absorption efficiency, respiration rate, and feces collection, to assess energy balance (S*cope for Growth*). At the end of the trial, individuals were dissected, and biometric measurements were taken to assess growth and standardize physiological rates. Tissue samples were also collected for further molecular analyses. All samplings were performed under permissions of competent authorities (SGBTM/BDM/AUTSPP/12/2024 and SGBTM/BDM/AUTSPP/12bis/2024).

*(Continued on next page)*

**Results and conclusions**

Among studied dietary treatments no significant differences in growth of individuals were observed. After one month under experimental conditions, individuals reached an average shell length of 70.7 ± 6.1 mm and a live weight of 5.6 ± 1.0 g. Clearance rates ranged between 1.2 and 2.3 $L \cdot ind^{-1} \cdot h^{-1}$ across all groups. However, significant differences were detected in absorption rate and absorption efficiency, both of which were lower in the group fed the *DL*–enriched diet. This reduced absorption capacity negatively impacted energy balance (S*cope for Growth*), resulting in a slight, though not statistically significant, reduction in growth. These results suggest that diet composition, particularly lipid enrichment, can affect physiological performance in *Pinna rudis*, and highlight the importance of optimizing feed formulations for successful captive rearing protocols applicable to *Pinna nobilis* conservation efforts.

The highest antimicrobial activity was recorded in the cell fraction of the microalgae cultures. The RL species shows an activity twice as high as that recorded in the other microalgae. In addition, the soluble fraction of the TS microalga exhibited the highest antimicrobial activity. Although these results do not correlate with the observed physiological differences, the higher antimicrobial potential of RL and TS adds value to these microalgae as components of the diet.

# ENHANCING SEAHORSE HIPPOCAMPUS ERECTUS PRODUCTION IN AQUACULTURE

Daniel Alexandre[1]*, Luísa Marques[1], Ricardo Calado[1]

[1] ECOMARE, Centre for Environmental and Marine Studies (CESAM), Department of Biology, University of Aveiro, Santiago University Campus, 3810-193 Aveiro, Portugal

Email: danielalexandre@ua.pt

## Introduction

Seahorses are unique marine fish species renowned for their distinctive morphology and reproductive behaviour. Due to their high commercial value and conservation concerns, seahorse aquaculture has gained attention as a sustainable alternative to wild collection. However, the successful maintenance and cultivation of seahorses, especially during their early life stages, presents numerous challenges. This study at CEPAM-ECOMARE (University of Aveiro, Portugal) aims to investigate key factors in the rearing of seahorses, namely *Hippocampus erectus,* including water quality, food supply, and tank management, to improve survival and optimize commercial production.

## Materials and Methods

The production of *Hippocampus erectus* at CEPAM-ECOMARE is performed in greenhouses, utilizing a 10,000 L Recirculating Aquaculture System (RAS). The seahorses are maintained in standard 200 L tanks, which are part of the RAS for efficient water circulation and optimal conditions for their growth and development. These tanks are equipped with aeration and water flow to create circular currents that enhance the distribution of *Artemia* sp. and prevent biofilm buildup. Tanks are cleaned regularly, with a standard disinfection protocol every 15 days or following abnormal mortality events. Water quality is monitored weekly, with natural seawater sourced from the adjacent coastal lagoon Ria de Aveiro (Portugal). For seahorse offspring, *Artemia* sp. metanauplii, enriched with omega-3 polyunsaturated fatty acids, particularly docosahexaenoic acid (DHA), are provided as primary food source to support early-stage development. As seahorses transition to juvenile and adult stages, they are gradually weaned onto frozen mysids (collected from the adjacent coastal lagoon), with commercial-size adults being fed with commercial frozen mysis. Seahorse offspring are placed in a single tank, and the sizesorting process begins after the 80$^{th}$ day to optimize population distribution.

## Results

Throughout the 7-month study, 18 hatching events occurred from two breeding pairs, resulting in a total of 2,942 newly born seahorses. From these, 11 batches of *Hippocampus erectus* were reared up to 80 days post-hatching, with survival ranging from 63% to 98%. The average survival across all batches was 88%, indicating a strong success in early-stage rearing. Mortality did not follow a consistent pattern, with large periods of no mortality followed by occasional mortality events. These results are particularly promising given the typically low survival associated with early-stage seahorse rearing, which is often under 30%. After hatching, seahorses are kept at a maximum population density of 1.5 individuals per L. After the 80$^{th}$ day, sorting is carried out to control the population density, ensuring it does not exceed one seahorse per L. Once seahorses reach an adult size (> 60 mm in total length), density is reduced to one seahorse per 2 L.

## Discussion

The high survival achieved in *Hippocampus erectus* aquaculture can be explained by the use of natural seawater, which, unlike what is commonly reported, did not result in significant health issues. As such, the composition of natural seawater may be more suitable than artificial seawater when it comes to seahorse production. Additionally, the management of food supply, particularly *Artemia* sp. metanauplii enriched in DHA, proved essential to support the early-stage development of seahorse offspring. The success of the simple tank system, with modifications concerning aeration and water flow, further suggests that advanced seahorse offspring rearing tanks may not be necessary to successfully culture this seahorse species. Population management, namely through sizesorting, helped to maintain stability in the tanks and a stress-free environment. Overall, these results highlight the importance of managing population density for successful seahorse rearing.

*(Continued on next page)*

**Figure 1:** Production systems and developmental stages of *Hippocampus erectus*. a) Recirculating Aquaculture System (RAS) in the greenhouses at CEPAM-ECOMARE, University of Aveiro; b) Adult male *Hippocampus erectus* carrying embryos in the brood pouch; c) Early-stage *Hippocampus erectus* juvenile (2-3 weeks old); and d) *Hippocampus erectus* juveniles (4 months old), feeding on frozen mysis.

## Conclusion

The rearing of *Hippocampus erectus* has provided valuable insights into effective aquaculture practices, which are worth being tested with other seahorse species. The high survival recorded highlights the potential for commercial-scale production of seahorses, provided that key factors, such as food supply, water quality, and stocking density, are carefully managed. Future research will focus on optimizing these parameters for even larger-scale operations and explore the potential of farmed seahorses for high-end uses.

# ABSOLUTE MONOCULAR DEBTH ESTIMATION FOR BIOMASS PREDICTION IN AQUACULTURE

Alexandrou, A., Christodoulou, F., Komninos, D., Ozdeger, T., Seferis, K.

Blue Analytics LTD
Kosta Loizou 12
Nicosia, Cyprus
Email: aalexandrou@blueanalytix.com

**Introduction**

Accurate fish biomass estimation is vital for sustainable and efficient aquaculture. Traditional methods (manual measurement or stereo cameras) are expensive, invasive, or complex. Monocular cameras offer a low-cost, widely available alternative, but they typically produce relative depth maps. This project develops an AI-based system to estimate absolute depth and fish biomass using monocular images, aiming to make biomass estimation more scalable and cost-effective in real aquaculture environments.

**Objectives**

Develop a monocular camera-based system to estimate fish biomass accurately in aquaculture environments. Leverage AI techniques to convert relative depth from monocular cameras into absolute depth. Reduce reliance on expensive stereo camera systems, enabling scalable and cost-efficient biomass monitoring.

**Methodology**

- Task 1: Depth Scaling.
  - Developed scaling models (linear, quadratic, cubic) using:
    - Office environment with known object positions.
    - Underwater aquaculture environment with a reference tile.
  - Applied offline and online scaling methods:
    - Offline: Derived a fixed scale from calibration data.
    - Online: Adjusted scaling dynamically during processing.
- Task 2: Fine-Tuning Monocular Model
  - Used Depth Anything V2 model.
  - Fine-tuned with 15,000 stereo camera frames from aquaculture cages.
  - Applied masks and depth constraints (1–2m) to focus on foreground fish.

  Output: SL (Standard Length) and biomass prediction derived from scaled/fine-tuned monocular depth.

**Results**

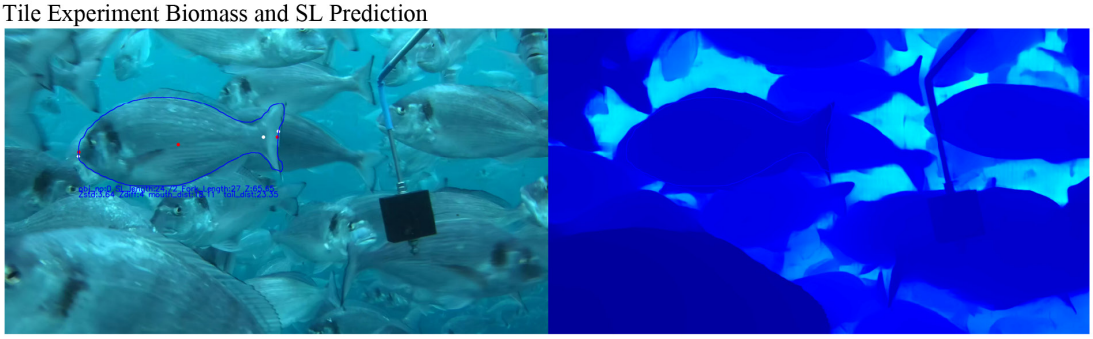
- Task 1: Depth Scaling
  - Office Environment (Fake Fish Test)
    - Best model: Cubic regression
    - Achieved SL error: 1.78 cm
  - Highest accuracy in controlled settings
  - Underwater Environment (Tile Scaling)
    - Offline scaling: More accurate but less adaptive
    - Online scaling: More consistent in changing conditions
    - After filtering for shallow depths (<90 cm):
      - SL MAE: 2.76 cm (offline) vs. 3.19 cm (online)
      - Depth MAE: 6.84 mm (offline) vs. 7.65 mm (online)
- Task 2: Fine-Tuning Depth Anything V2
  - Best model: Model_v2 (max depth = 1m)
  - Achieved:
    - SL MAE: 1.48 cm
    - Depth MAE: 3.94 mm
    - Biomass prediction within 8% of ground truth
  - Performed well across multiple aquaculture cages

*(Continued on next page)*

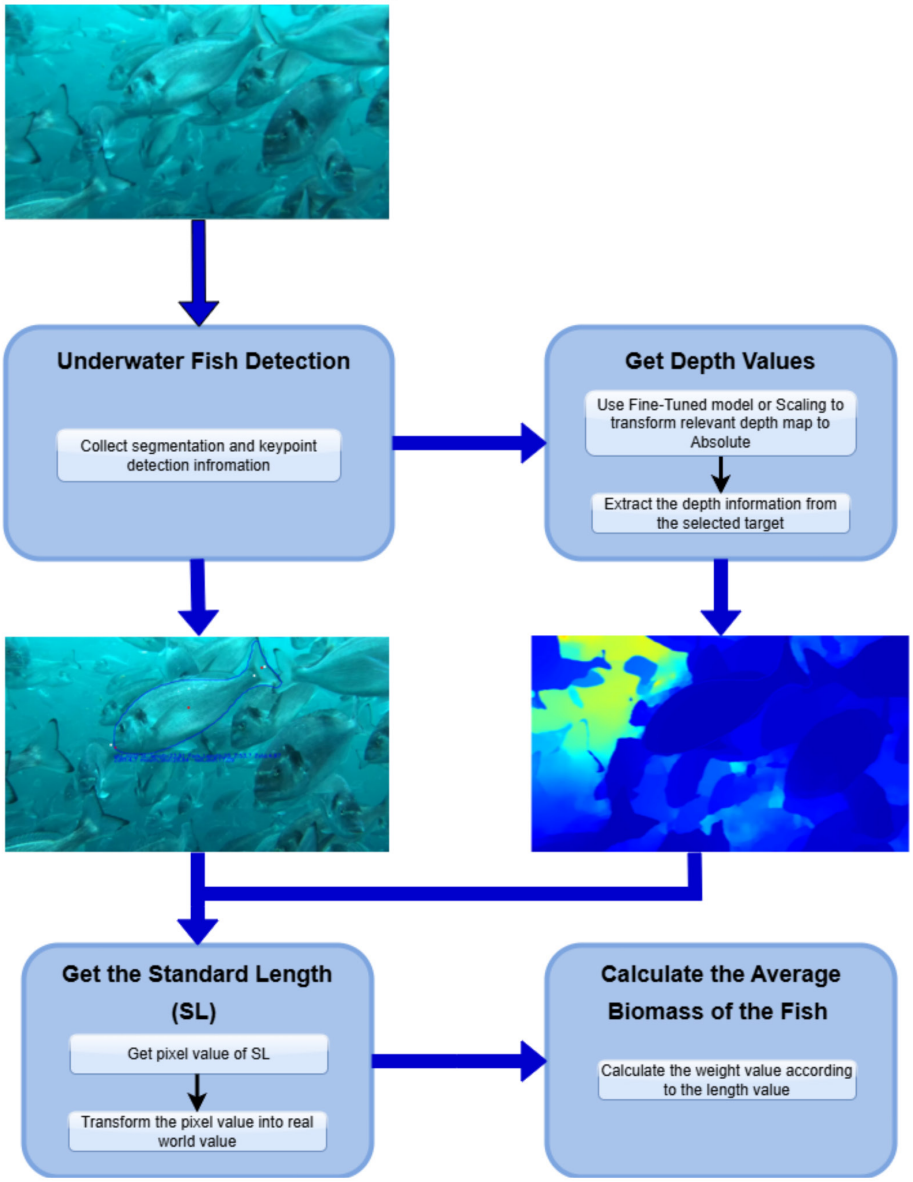
**Conclusion**

Monocular cameras, when properly scaled or fine-tuned, can achieve biomass estimation accuracy comparable to stereo systems. The tile-based scaling method (especially offline) provided a practical solution for real aquaculture conditions, with strong results after filtering for shallow depths. Fine-tuning the Depth Anything V2 model with domain-specific stereo data significantly improved accuracy, with SL and biomass errors consistently below 2 cm / 10%. The best-performing model (1m max depth) proved to be both accurate and relatively robust across different aquaculture cages. This work shows strong potential to replace expensive, high-maintenance stereo camera systems with scalable monocular setups.

Tile Experiment Biomass and SL Prediction



The flowchart of fish biomass estimation



*(Continued on next page)*

Task 1: SL and Biomass Results -Underwater Experiments (Tile Scaling)

| Scaling method | Predicted Average Biomass (g) | Predicted Average SL (cm) | Predicted SL STD (cm) |
|---|---|---|---|
| Offline Scaling | 500.94 | 25.90 | **3.09** |
| Online Scaling | **471.00** | **25.40** | 3.95 |
| Ground truth | 421.58 | 24.52 | 2.33 |

Task 1: SL and Depth Error for Predicted Depth Values < 90

| Scaling method | SL MAE | SL Error STD | Depth MAE | Depth Error STD |
|---|---|---|---|---|
| Offline Scaling | **2.76** | 2.97 | **6.84** | 7.26 |
| Online Scaling | 3.19 | **2.56** | 7.65 | **6.17** |

Task 2: Model Performance Comparison on SL and Biomass

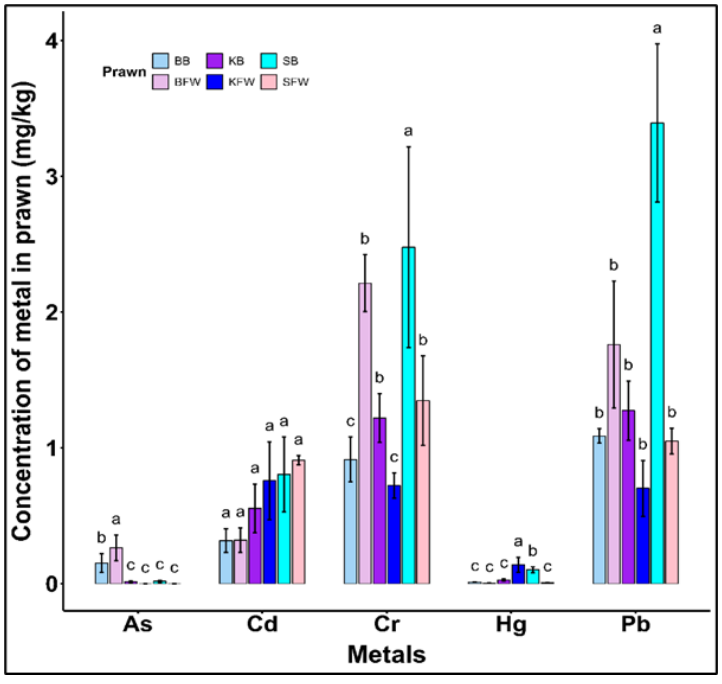
# TOXIC METAL CONTAMINATION IN FRESHWATER AND BRACKISH WATER PRAWNS (*Macrobrachium rosenbergii*) FROM SOUTHWESTERN BANGLADESH: ECOSYSTEM EXPOSURE AND HUMAN HEALTH RISK ASSESSMENT

M. Lokman Ali* and Md. Rafiqul Islam

*Patuakhali Science and Technology Universit
Dumki, Patuakhali-8602, Bangladesh
Email: lokman@pstu.ac.bd

Bangladesh is acknowledged as a prominent nation in fish and shellfish production, attributed to its distinctive geographical features, including extensive rivers, wetlands, and a lengthy coastline, which create a conducive habitat for various fish species, thereby supporting numerous fisheries that constitute a vital sector of the Bangladeshi economy. Bangladesh is acknowledged as a leading country in global aquaculture, particularly in shellfish production. Prawns (*Macrobrachium rosenbergii*), often referred to as 'white gold,' are a key driver of this sector. However, rising global concerns over heavy metal contamination can be a threat to this sector.

To address these issues, we analyzed five toxic metals (As, Cd, Cr, Hg, Pb) in prawns, water, and sediment samples using the AAS method from freshwater and brackish water zones in Bagerhat, Khulna, and Satkhira district of Bangladesh. Statistical analysis revealed no significant differences (P>0.05) in toxic metal concentrations in prawns when comparing tissue types (CT vs. MU), salinity (freshwater vs. brackish water), or sampling zones (Bagerhat, Khulna, and Satkhira). Except As and Hg, all trace metals exceeded the maximum permissible limits proposed by different authorities. In the case of sediment, only Cr and Hg exceeded the allowable limits, where Pb was totally absent in water and less polluted from prawn and sediments. The BAF (2.031-76.667) was contained far below the threshold, where the BSAF values (0.014-10.2) suggested that metal actively bioaccumulated from sediment. Sediment samples exhibited the highest Metal Pollution Index (MPI) values (1.0-1.8), compared to prawn (0.14-0.8) and water (0.02-0.22). The extent of sediment contamination was assessed through the analysis of several indices, including the Pollution Load Index (PLI), Contamination Factor (CF), modified Contamination Degree (mCd), Ecological Risk Index (RI), Geoaccumulation index (), and Toxic Risk Index (TRI). No health risks were identified for either adult or child populations from the Estimated Daily Intake (EDI), Non-carcinogenic Risk (THQ), and Cancer Risk (CR) assessments. While the study suggests no immediate health hazard, it indicates that government and non-government institutions should ensure continued monitoring of metal toxicity and take proactive measures to prevent contamination in the future.This research provided an adequate overview of the heavy metal contamination in different environmental matrices, although further study is necessary to design the conceptual framework model for heavy metal contamination in an aquaculture field to better mitigate the hazards and risks in sustainable aquaculture



# HIGH ENVIRONMENTAL AMMONIA REGULATES THE EARLY LIFE DEVELOPMENT OF ATLANTIC SALMON (*Salmo salar*)

H.R. Alipio[1]*, B.S. Sæther[1], H. Tveiten[1], B.C. Nybakk[1]

[1]UiT, The Arctic University of Norway
9019, Tromsø, Norway

*Email: hanna.r.alipio@uit.no

## Introduction

The mechanisms of ammonia excretion and its associated toxicity have been extensively studied in freshwater fish; however, comparable investigations in anadromous species, particularly during early developmental stages of Atlantic salmon (*Salmo salar*), remain limited. Elevated environmental ammonia is highly toxic to fish, disrupting critical physiological processes such as osmoregulation, respiration, metabolism, neurotransmission, and cellular function, which can compromise health and even lead to mortality. However, exposure to high environmental ammonia during embryonic development may induce phenotypic plasticity, potentially conferring long-term benefits for stress resilience later in life. This study aimed to elucidate the patterns of ammonia transport in Atlantic salmon embryos and larvae up to 976 day-degrees (DD) post-fertilization. A secondary objective was to characterize the mRNA expression of key ammonia transporters (Rhag, Rhbg, and Rhcg), the urea transporter (UT), H+-ATPase, Na+/K+-ATPase, and sodium-hydrogen exchangers (NHE3 and NHE2) during early development under exposure to three sub-lethal ammonia concentrations. In addition, the study investigated whether ammonia exposure affects the cellular stress response by analyzing the mRNA expression of heat shock proteins HSP70 and HSP90.

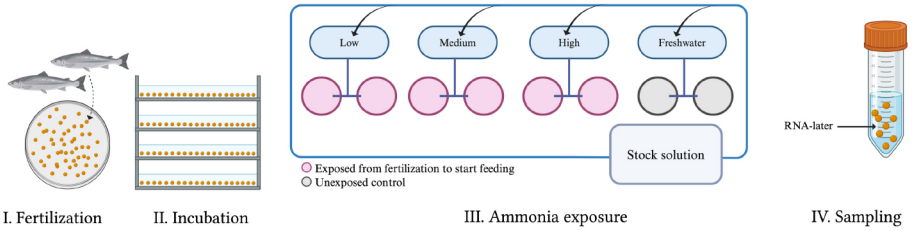
## Materials and methods

An ammonia exposure trial was conducted by fertilising a batch of Atlantic salmon eggs followed by the exposure to three levels of ammonia (low: 22 µg/L, medium: 75 µg/L, and high: 148 µg/L) until the stage prior to start feeding (976 DD). Samples were taken from six developmental timepoints for mRNA expression analysis of important genes responsible for ammonia transport, urea excretion and cellular stress response. The spatial localization of ammonia transporters was also examined at two key developmental stages: hatching (525 DD) and near complete yolk absorption (900 DD), using immunohistochemistry.

## Results and Discussion

The results demonstrated that Atlantic salmon embryos are primarily ammoniotelic throughout development, with ammonia serving as the predominant nitrogenous waste product. The mRNA expression of Rhesus glycoprotein (Rh) genes, particularly Rhag and Rhcg, as well as the UT gene, showed strong alignment with the ontogeny of ammonia and urea excretion rates observed in other salmonid species. However, exposure to elevated ammonia levels significantly altered the expression patterns of these transporters suggesting that environmental ammonia influences the regulation of nitrogenous waste excretion.

Spatial localization revealed that Rhag was expressed in the developing gills, yolk sac, and operculum, while Rhbg was localized to the gills and oral cavity. Rhcg was detected in the sub-operculum and skin. These findings indicate that ammonia excretion is the primary mechanism of nitrogenous waste elimination during early development in Atlantic salmon, with Rhesus glycoproteins playing a pivotal role in ammonia transport via the gills and yolk sac. This process is likely facilitated by the coordinated activity of H+-ATPase, Na+/K+-ATPase, and sodium-hydrogen exchangers.



*(Continued on next page)*

Furthermore, the upregulation of HSP70 and HSP90 in response to elevated ammonia concentrations suggests that ammonia exposure induces a cellular stress response during early development. This highlights the potential physiological impacts of environmental ammonia on developing salmon and underscores the importance of understanding how early exposure shapes stress-related molecular pathways.

**Conclusion**

This study reveals that elevated environmental ammonia regulates the early development of ammonia transport and excretion mechanisms in Atlantic salmon. Early exposure to ammonia alters the molecular responses of developing embryos, potentially influencing their ability to handle stress later in life. These findings provide valuable insights into the physiological and molecular adaptations of Atlantic salmon to environmental stressors during critical developmental stages.

**Introduction**

Interest in cod farming is once again growing in Norway, driven by a new generation of domesticated cod selected for improved growth through breeding programs. Despite these advancements, several challenges remain—one of the most pressing being the control of sexual maturation, which can compromise growth performance, fish health, and pose environmental risks. Indeed, in cod (*Gadus morhua*) farming, fish are typically reared in open sea cages. In case of individuals reaching maturity, they may release fertilized eggs either during a spawning event occurring in the cages or after escaping. This could result in a possible interaction with wild cod and genetic pollution of the local cod stocks in Norway. One proposed mitigation strategy is the use of continuous light (LL), or LL and shading of natural light (at surface or using submergence) which is known to delay maturation of cod in cages. Additionally, the use of standard feeds aimed at maximizing somatic growth may influence reproductive output in maturing fish when compared to broodstock diets. However, the extent to which these effects persist in the current domesticated cod strains—now in their 6th to 8th generation—remains unclear.

**Methods and setup**

To improve control of sexual maturation in farmed cod through light and submergence strategies, we employed surface cages exposed to strong continuous light (LL, 2500 W) and submerged sea cages positioned at 30 m depth (away from strong natural daylight), also under LL conditions (600 W). Additionally, two dietary treatments - broodstock (Vitalis Prima, Skretting) and standard (Amber Neptun, Skretting) diets - were tested under natural light (NL) conditions. For each treatment group, 240 to 480 cod with an average weight of 1.5 to 2 kg were stocked in cages in September 2024. LL-fish were held under continuous light in indoor tanks before transfer while NL-fish were kept under natural photoperiod. Fish from each group were sampled every six weeks for growth measurements, blood and tissue collection, and assessment of sexual maturation through various biological indicators. Parasite prevalence was also monitored, and a welfare score was developed to assess overall fish health. At the onset of the spawning season, mature fish were transferred to indoor tanks equipped with egg collectors, using a male-to-female ratio of 2:1. As a reference, wild cod captured near the cages were maintained in a separate tank under similar conditions. Egg volume and fertilization rates were recorded daily. Additionally, newly fertilized eggs were sorted and incubated in NUNC plates at 6 °C to monitor survival until hatching, determine hatching success and evaluate larval morphometry at hatch.

**Results and discussion**

At 2.5 years old, fish reached an average weight of 3.7 kg with no significant differences observed between dietary treatments. Preliminary welfare assessments - based on indicators established for salmon - suggest that the welfare of farmed cod was generally acceptable, despite the occurrence of some skeletal deformities, particularly in the backbone and head regions. Consistent with previous trials, parasite prevalence, specifically *Caligus*, was higher in LL-fish held in submerged cages. Sexual maturation was first detected in NL-individuals, while those in LL treatments entered early stages of maturation 5 months later. Both males and females underwent maturation across treatments.

Egg production during the spring spawning season (NL treatment) varied, with females fed the broodstock diet producing a greater egg volume compared to those on standard growth diets. Fertilization rates were lower and more variable in farmed cod than in the wild reference group. Survival and hatching rates were also treatment-dependent. Overall, reproductive output and developmental success were superior in wild cod compared to farmed groups. Within farmed treatments, eggs from broodstock-fed fish outperformed those from standard-fed fish, which showed poorer fertilization, survival, and developmental outcomes.

Our results indicate that both light regime and diet significantly influence the reproductive performance and developmental success of farmed cod. Continuous light effectively delayed sexual maturation, while standard diets had a negative impact on egg quality and larval outcomes compared to broodstock diets. Nonetheless, a substantial proportion of larvae survived post-hatching across treatments, suggesting that accidental spawning in cages—or following escape events—could contribute to the presence of farmed-origin individuals in the wild.

# GENOMIC ADMIXTURE AND LOCAL THERMAL ADAPTATION SHAPE LARVAL SURVIVAL IN EUROPEAN SEA BASS: IMPLICATIONS FOR SELECTIVE BREEDING UNDER CLIMATE CHANGE

## Introduction

The European sea bass (Dicentrarchus labrax) is a key species of Mediterranean aquaculture and has undergone rapid domestication and selective breeding in the past two decades (Vandeputte et al., 2019). European sea bass breeding programmes are based on genetic resources gathered from three remarkable populations, Atlantic (AT), Western Mediterranean (WM), and Eastern Mediterranean (EM), formed through historical isolation, from which emerged two ancestral lineages (Atlantic - ATL, and Mediterranean - MED), followed by a secondary contact (Duranton et al., 2018). These populations characterized by a gradient genomic introgression between the two ancestral lineages, are differentially adapted to regional temperatures. Such introgression variation may impact larval fitness and complicate selective breeding strategies under shifting climatic conditions.

## Materials and Methods

Using a common garden design, we reared ~57,600 larvae from AT, WM, and EM origins under four thermal regimes (*rAT*, *rWM*, *rEM*, and *rAQUA*) mimicking natural and hatchery environments. Over 6,200 juveniles were genotyped with a 57K SNP array (Griot et al., 2021)identification of genomic regions involved in the resistance could improve the efficiency of selective breeding. The aim of this study was to identify quantitative trait loci (QTL, and ancestry was reconstructed via ADMIXTURE (Alexander et al., 2009)derived from multi-locus genotype data, can be used to perform a statistical correction for population stratification. One popular technique for estimation of ancestry is the model-based approach embodied by the widely applied program structure. Another approach, implemented in the program EIGENSTRAT, relies on Principal Component Analysis rather than model-based estimation and does not directly deliver admixture fractions. EIGENSTRAT has gained in popularity in part owing to its remarkable speed in comparison to structure. We present a new algorithm and a program, ADMIXTURE, for model-based estimation of ancestry in unrelated individuals. ADMIXTURE adopts the likelihood model embedded in structure. However, ADMIXTURE runs considerably faster, solving problems in minutes that take structure hours. In many of our experiments, we have found that ADMIXTURE is almost as fast as EIGENSTRAT. The runtime improvements of ADMIXTURE rely on a fast block relaxation scheme using sequential quadratic programming for block updates, coupled with a novel quasi-Newton acceleration of convergence. Our algorithm also runs faster and with greater accuracy than the implementation of an Expectation-Maximization (EM and APIS (Griot et al., 2020). Parental ATL ancestry was used to define high vs. low introgression groups (POP+ / POP−). Larval survival was analyzed using generalized linear and logistic models, including quadratic regression to estimate temperature optima.

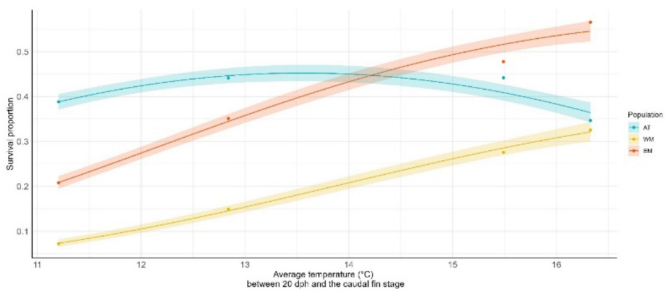

**Fig 1.** Fig. 1. Larval survival as a function of temperature in three European sea bass populations. Lines show logistic regression fits of survival rates to average temperature between 20 dph and caudal fin stage. Shaded areas: 95% CI. AT = Atlantic, WM = Western Mediterranean, EM = Eastern Mediterranean.

*(Continued on next page)*

**Results and Discussion**

The interaction between thermal regime and population origin had a highly significant effect on larval survival ($P < 2.2 \times 10^{-16}$), highlighting local thermal adaptation and genetic divergence among the three sea bass populations. AT larvae showed the highest survival in colder regimes (rAT and rWM), with an estimated thermal optimum of 13.6°C (Fig. 1). Conversely, EM larvae performed best in warmer regimes (rEM and rAQUA), with predicted optima near or above 17.8°C. These dome-shaped thermal reaction norms suggest divergent selection histories aligned with regional spawning periods and sea surface temperature profiles.

WM larvae consistently had the lowest survival across all regimes, with no clear optimum, likely due to high and heterogeneous genomic admixture causing outbreeding depression. These differences are unlikely to stem from egg size, larval length, or prey preference, and instead point toward disrupted genomic architecture or hybrid incompatibilities.

Introgression from the alternate lineage significantly impacted survival in both AT and EM populations. In AT, offspring from less introgressed parents (POP−, lower MED ancestry) had higher survival, especially under colder conditions. Similarly, EM larvae with lower Atlantic (ATL) ancestry survived better in warm regimes. Chi-squared tests and ancestry comparisons confirmed purging of the minor lineage, MED in AT and ATL in EM, highlighting directional selection against introgressed genomes and reduced hybrid fitness.

In WM, no such purging was detected, likely due to genome-wide saturation with introgressed tracts. This persistent admixture may prevent the elimination of maladaptive alleles, explaining WM's poor survival even under its native thermal regime. These patterns align with previous studies reporting purifying selection against Atlantic ancestry in Mediterranean populations.

# SIMULATING GROWTH AND SIZE VARIABILITY OF *Sepia officinalis* HATCHLINGS FROM DATA ABOUT ZOOTECHNICAL VARIABLES AND BIOENERGETICS UNDER CAPTIVITY

**Introduction**

The cephalopod species *Sepia officinalis* has been extensively investigated in relation to growth under captivity. Data on size, ingestion rate, conversion rate, bioenergetics and survival are particularly abundant for the first feeding period. The present work aims to integrate published data (Grigoriou and Richardson, 2008, 2009; Bureau et al., 2002, Domingues et al., 2001a) on: size at hatching, bioenergetics, and ingestion rate, into a stochastic model to understand the effect of the initial distribution of body sizes on the temporal pattern of body size dispersion during the first feeding period of *S. officinalis*.

**Materials and methods**

The stochastic model simulated a growth experiment with 15 groups (or tanks), each group with 30 cultured hatchlings reared during the first feeding period (20 days) in an Excel spreadsheet. The experimental factor was the initial coefficient of variation of body wet weights ($CV_{WW0}$) of the group. Three factor levels of $CV_{WW0}$ (10, 20 and 30 %) were replicated five times (five groups). For each group, initial body wet weights (WW) were extracted from a normal distribution with mean 0.1 g, and one of the $CV_{WW0}$ levels. Three dependent variables were calculated for each group: i) the mean specific growth rate (SGR), ii) the mean $CV_{WW}$, and iii) the final $CV_{WW}$. Temperature, ingestion rate (IR%) and prey were based on Domingues et al. (2001a). Temperature was set at 27.5 ºC. The IR% (under ad libitum feeding) of each individual in each culture day was extracted from a normal distribution with mean IR% = 21.259 $WW(g)^{-0.173}$, and $CV_{IR\%}$ = -0.0596 WW(g) + 0.4304. Prey was assumed to be mysids with an energy content of 19.5 J/mg of dry matter. Maintenance energy of each (resting) individual in each day was based on bioenergetic principles (Bureau, 2001), data on energy losses due to excretion and the specific dynamic action, and data on standard metabolism (Grigoriou and Richardson, 2008, 2009) which depended on body dry weight and temperature. Net conversion rate of biomass was assumed to be constant (Wells and Clarke, 1996), and it was estimated to be 0.585 from experimental data on growth, ingestion and maintenance ration in *S. officinalis* hatchlings reared at 27.5 ºC. Survival rate was set at 100 %, according to literature. To determine the increase in WW of a given individual in a given day, the IR% was first simulated. Subsequently, if energy ingestion was below maintenance energy, the energy difference was assumed to come from cuttlefish tissues, and negative growth is attained. On the contrary, if energy was above maintenance, the WW for the next day was calculated according to energy content, and biomass gross conversion rate in *S. officinalis* hatchlings. This process was iterated for each hatchling in each group until day 20. Data on SGR, mean and final CV were analyzed by one-way ANOVA tests.

**Results**

The mean SGR was 10.03 ± 0.23 % day-1 for the three treatments. $CV_{WW0}$ did not affect the mean SGR ($p=0.376$) but, as expected, it exerted a significant effect on the mean $CV_{WW}$ along the experiment ($p < 0.001$), and not so clearly in the case of $CV_{WW}$ at day 20 ($p = 0.088$). In general, the higher the $CV_{WW0}$, the higher the $CV_{WW}$ at any day, but this difference was gradually getting shorter over time.

*(Continued on next page)*

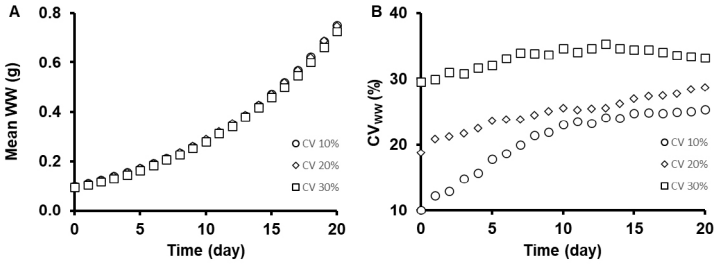

Fig. 1. Simulated growth of *S. officinalis* hatchlings. A. Mean wet weights. B. Mean $CV_{WW}$

**Discussion**

The mean SGR of 10.03 ± 0.23 % day$^{-1}$ for the three simulated treatments was reasonably close to the experimental mean SGR of 9.1 ± 3.1 % day$^{-1}$ for different individuals, reported by Domingues et al. (2001a), under similar culture conditions. A general characteristic of empirical data about growth of cuttlefish hatchlings is an increase in weight CV over time, which subsequently slows down or even changes into a $CV_{WW}$ drop (Koueta et al., 2000; Domingues et al., 2001b, 2003, 2004; Correia et al., 2008). These empirical data showed a mild positive Spearman correlation between the $CV_{WW}$ at day 0 and $CV_{WW}$ at days 10-15 despite the variations among experimental designs from different authors. The temporal pattern of $CV_{WW}$ in our simulations shows similar features, since we obtained an initial increase in $CV_{WW}$ that levels off towards the end of the first feeding period. Therefore, this work supports the usefulness of stochastic models based on zootechnical data, and bioenergetic principles to simulate body size variability in groups of cultured *S. officinalis* hatchlings.

**Introduction**

The remarkable growth that aquaculture has experienced in the last decade (FAO, 2024) requires the adoption of sustainable practices, with diversification through new low-trophic level species and improved feeding techniques being essential.

In Spain, despite the success of fish and mussels farming, crustacean aquaculture remains limited. Early domestications attempts were made in the 70's for caramote prawn, *Penaeus (Melicertus) kerathurus*, a high-value species in the Mediterranean, however, results were unsuccessful (Muñoz & San Feliu, 1978). Nowadays, scientific&technological advances offer new opportunities to reconsider the farming potential of caramote prawn.

This study aims to expand knowledge of *P. kerathurus* biological rhythms—key for welfare and farming efficiency (Peixoto et al., 2025)—by analyzing feeding activity rhythms under fixed-time manual feeding or a novel photocell-activated self-feeding system.

**Material and Methods**

Four *P. kerathurus* individuals obtained from local fisheries at San Carlos de la Rápita (Tarragona, Spain) were kept individually in 30 L tanks (40 x 25 x 30 cm, with 5 cm sand) with filtered, aerated water under a 13h:11h light-dark cycle (light on at 8:00 h) at the marine aquaculture laboratory of Tilamur S.L. (Lorquí, Murcia). Water quality was monitored daily (salinity, temperature, pH, and dissolved oxygen). Nitrite and nitrate were measured twice weekly (JBL PROAQUATEST COMBISET Marin) with 60% water exchanges every week.

After a one-week acclimation with daily hand-feeding (28% of tank biomass) on a raised platform, to train prawns to feed in a designated feeding zone. Two experiments were done: (1) manual feeding at 19:00 h (20 days) and (2) with self-feeding (22 days). Feeding activity was recorded using photocells and analyzed with El Temps software (v1.291) to produce actograms and calculate mean waves.

**Results & Discussion**

The recordings showed under fixed feeding, 76.3 ± 6.3% (mean ± SD) of total feeding activity occurred at night. The mean wave (Fig. 1) revealed increased feeding activity at specific times, with a first peak around 18:00 (anticipatory activity) and a larger second peak between 19:50 and 20:50 (eating activity), accounting for 68.25% of daily activity.

For the second experiment, a novel self-feeding system (Fig. 2) with a food dispenser triggered by a photocell above the feeding platform was designed to deliver food on prawn demand. To prevent overfeeding, feeding was limited to one activation every two hours during the night. Data were recorded with a custom monitoring program.

Under self-feeding, activity was mostly nocturnal (76.8 ± 9.5% (mean ± SD)), showing four peaks of activity, the biggest one at night onset (31.6 ± 1.9%). Certain cognitive capacity was observed, since they learned to operate the feeder by regulating their intake according to their biological rhythms.

## Introduction

Due to the growing demand driven by aquaculture expansion, the supply of marine-derived ingredients for aquafeeds can no longer keep pace, prompting a shift toward alternative raw materials. This transition has led to increasingly complex feed formulations, which may impact fish growth, nutrient absorption, and overall health. In this context, maintaining gut health is vital, as disruptions in gut function can impair nutrient utilization and immune function, raising the risk of disease outbreaks. To overcome these challenges, protein hydrolysates (PH), rich in essential amino acids (AAs) and bioactive peptides (<10 kDa), have emerged as promising functional ingredients in aquafeeds, providing benefits beyond their nutritional value, enhancing animal resilience. Serotonin (5-hydroxytryptamine, 5-HT), a neurotransmitter mainly produced in the gut, regulates key physiological processes, including appetite, gut motility, and mucus secretion. Certain AAs have been shown to modulating serotonergic activity, although underlying mechanisms remain unclear. Moreover, PH have shown potential in modulating intestinal physiology and integrity through the regulation of serotonin metabolism. A better understanding of serotonin metabolism, and how it can be influenced by diet, is crucial for developing effective nutritional strategies to preserve gut health, under ever evolving aquafeed formulation. Thus, this study hypothesizes that dietary PHs can improve gut physiology and barrier integrity in gilthead seabream (*Sparus aurata*) through modulation of the serotonergic metabolism.

## Material & Methods

Four diets were formulated: a commercial-like diet (CTRL) and three experimental diets (INSECT, FISH, SWINE), in which 3% of high-quality commercial PH was replaced with locally sourced agri-food-derived PHs. Juvenile fish were fed these diets thrice daily for 88 days and, at the end of the growth trial, anterior intestine samples were collected. Gut integrity was evaluated histologically using both light and transmission electron microscopy (TEM). Gene expression analyses in the anterior intestine targeted key serotonin-related genes (involved in 5-HT synthesis, transport, and receptor activity), alongside markers of gut integrity and immune response.

## Results & Discussion

All diets were well accepted, with no differences in voluntary feed intake. Fish fed the INSECT and SWINE diets exhibited significantly higher final body weight compared to CTRL. Histomorphological parameters of the anterior intestine assessed under light microscopy, such as absorption area, submucosa thickness, *villus* length, goblet cell (GC) quantification and size, revealed no significant differences among treatments. Histomorphology analyses were further supported by TEM analyses, that revealed no observable differences in the epithelial cells, presenting a regular morphology, with an intact epithelium barrier. Enterocytes showed a distinct brush border, orderly nuclear alignment, and a tall columnar morphology, and intact intercellular junctions, with no signs of disruption. Moreover, the expression of *tjp1*, a gene that encodes a tight junction protein involved in regulating the movement of macronutrients across epithelial cells, did not differ among treatments, supporting observed gut morphology and cellular architecture. Fish fed the SWINE diet showed higher expression of *slc6a4a*, a gene associated with serotonin transport. Additionally, *muc2* and *il6* were also upregulated in these fish. This suggests that an increased re-uptake of serotonin may be associated with increased mucus production and modulation of immune and inflammatory response. These findings are consistent with other animal models, where serotonin has been shown to stimulate intestinal mucin secretion. In

*(Continued on next page)*

contrast, INSECT fed fish also showed an upregulation of *muc2* expression, but serotonin related genes remained unaffected. Notably, despite a trend ($p = 0.054$) toward fewer GCs, which remained unchanged in size, *muc2* expression was upregulated in fish fed the INSECT and SWINE diets. Thus, this could reflect a compensatory mechanism where increased transcriptional activity helps sustain mucus production despite fewer GCs. Gene expression results will be further discussed to clarify the links between gut integrity, immune response and 5-HT system response.

**Conclusion**

This study showed that PHs derived from swine by-products and insect meal promote growth in gilthead seabream while preserving intestinal integrity. All PH supported a healthy intestinal architecture, with enterocytes maintaining normal morphology and tissue organization. Although a slight reduction in goblet cell number was observed, the concurrent upregulation of *muc2* expression in INSECT and SWINE suggests an adaptive mechanism that maintains mucosal protection and secretory function. Moreover, fish fed the SWINE diet showed higher expression of genes related with serotonin transport, suggesting a potential modulatory effect on serotonin-mediated gut functions. These findings point to a broader impact of this PH on gut homeostasis and neuroimmune communication. Collectively, these results highlight the value of PHs, particularly SWINE and INSECT, as functional ingredients in aquafeeds, with the potential to support not only growth but also gut health and integrity. Ongoing molecular analyses will further clarify the mechanisms by which PHs influence serotonin pathways and contribute to long-term gut well-being in aquaculture species.

## Introduction

Insects such as the yellow mealworm (*Tenebrio molitor*) are increasingly recognized as sustainable alternative ingredient in aquafeed production, due to their high protein content, well-balanced amino acid profile, and valuable mineral and vitamin composition [1]. Additionally, mealworm meal (MM) production has a relatively low environmental footprint [2]. However, the economic feasibility of MM production remains a challenge, prompting the exploration of cost-effective rearing strategies. One promising strategy involves incorporating agro-industrial byproducts insect rearing substrates. This strategy may reduce production costs while simultaneously influencing the yield and nutritional quality of the final product [3, 4]. Among this byproducts, spent mushroom substrate (SMS), the primary residue of mushroom cultivation, [5] has been identified as a sustainable alternative to traditional substrates like grains and seeds [6], potentially minimizing nutrient losses across the production chain.

This study aimed to evaluate the use of MM produced based on larvae partially reared on SMS, compared to conventional MM, as fishmeal replacement in juvenile rainbow trout (*Oncorhynchus mykiss*) diets.

## Materials and methods

Two different yellow MM (pre-pupae stage) were evaluated. One MM (CC-MM; protein 51.9%, lipids: 32.8%) was produced using a commercial rearing cereal-based substrate (CC), while the test MM (SMS-MM; protein 53.1%, lipids: 24.2%) was produced with a substrate composed of 80% commercial substrate and 20% SMS. Five isoproteic (45%) and isolipidic (22%) experimental diets were formulated. A control diet (CTRL) was formulated to resemble a conventional commercial trout diet, containing 20% fishmeal. Four additional diets were formulated by partially or fully replacing fishmeal with either CC-MM or SMS-MM at inclusion levels of 12.5% or 25%, corresponding to 50% or 100% of fishmeal, respectively (diets: CC12.5, CC25, SMS12.5, and SMS25). A feeding trial was conducted using juvenile rainbow trout (initial body weight: 11.4 ± 1.5g trout$^{-1}$) with 20 fish randomly assigned to each of 15 fiberglass tanks (120L) within a recirculating aquaculture system (RAS). Fish were hand-fed to apparent satiation twice daily over an eight-week period. At the end of the trial, growth performance, whole-body composition and digestive enzymes activity were evaluated. Simultaneously, a digestibility trial was conducted (42.6 ± 15.6 g trout$^{-1}$) reared in a separated RAS with 60 L capacity fiberglass tanks, each connected to a faecal sedimentation column (Guelph system), to determine the apparent digestibility coefficients (ADC) of the experimental diets

## Results

Fish fed diets containing SMS-MM exhibited significantly higher ADC for dry matter, protein, ash, phosphorus, and energy compared to those fed diets with CC-MM. Irrespective of the MM type, increasing the inclusion level from 12.5% to 25% further improved nutrient and energy digestibility. No significant differences were observed in overall growth performance among dietary treatments. However, voluntary feed intake was reduced in fish fed the SMS25 and CC25 diets compared to the CTRL group. In contrast, fish fed CC25 diet showed improved feed efficiency, higher protein efficiency ratio and a lower

*(Continued on next page)*

hepatosomatic index relative to those fed the CTRL diet. Whole-body lipid and energy contents were significantly higher in those fed SMS-MM-based diets compared to CC-MM-based diets. Moreover, independent of MM type, a 25% dietary inclusion led to higher whole-body lipid and energy contents and reduced ash and phosphorus contents compared to 12.5% inclusions. Regarding digestive enzymes activities, no significant differences were observed in α-amylase activity among treatments. However, fish fed 25% MM diets exhibit elevated lipase activity compared to those fed 12.5% MM diets, while fish fed SMS25 showed higher trypsin activity compared to the CTRL group.

**Conclusion**

The dose-dependent inclusion of both types of mealworm meal (MM) had no significant effect on the growth performance of juvenile rainbow trout, although feed intale was reduced at the 25% inclusion level. Mealworm meal produced using rearing substrate partially composed of spent mushroom substrate (SMS) demonstrated comparable nutritional adequacy to that produced with conventional substrates. However, the inclusion of both MM influenced nutrient utilization, with distinct effects observed on lipid deposition, digestibility, and digestive enzyme activity. These findings highlight the potential of incorporating agro-industrial byproducts into insect rearing substrates for sustainable aquafeed production, aligning with the objectives of the EU's Farm-to-Fork strategy.

**Introduction**

The yellow mealworm (*Tenebrio molitor*), an emerging alternative ingredient for aquafeeds with potential to influence the immune and oxidative status of fish [1]. Modifying the rearing substrate used in mealworm production is a promising strategy to enhance productivity, which may modulate not only the nutritional value, but also the functional properties of the end-product [2, 3]. Spent mushroom substrate (SMS), the main waster of mushroom production, presents a sustainable alternative to conventional cereal-based rearing substrates traditionally used in mealworm farming [4, 5]. This study aimed to evaluate the impact of larval rearing substrate composition on the bioactive and functional properties of mealworm meal (MM). Additionally, the effects of dietary inclusion of both MM types on the immune and oxidative status of juvenile rainbow trout (Oncorhynchus mykiss) were evaluated.

**Materials and methods**

Two different MM were used, a commercial MM (CC-MM, crude protein 51.9%, crude lipids: 32.8%) and a teste MM (SMS-MM, crude protein 53.1%, crude lipids: 24.2%), produced using a substrate composed by 80% of commercial rearing subtrate and 20% of SMS. The bioactive and functional properties of CC-MM and SMS-CC were assessed in an *in vitro assay*. Functional compounds were extracted from both MM using three different extraction methods: distilled water, 1:1 acetone and methanol mixture, or dichloromethane. The antimicrobial activity of the crude extracts was tested against six fish-relevant reference microorganisms (*Aeromonas hydrophila* DSM 3018, *Yersinia ruckeri* ATCC 29473, *Listonella anguillarum* ATCC 19264, *Lactococcus garvieae* DSM 20684, *Tenacibaculum maritimum* ATCC 43397 and *Edwardsiella tarda* DSM 30052) using the agar-based disk diffusion method [6]. A growth trial was then conducted to determine the effect of the dietary inclusion of both MM types on the immune and oxidative status of rainbow trout. Five isoproteic (45%) and isolipidic (22%) experimental diets were formulated: a control diet (CTRL) similar to a traditional commercial trout diet and four test diets based on the CTRL diet, including 12.5% or 25% of CC-MM or SMS-MM, replacing either 50% or 100% of fishmeal, respectively (CC12.5, CC25, SMS12.5, SMS25 diets). Fifteen groups of 20 juvenile rainbow trout (11.4 ± 1.5g) were randomly distributed over 15 fiberglass tanks (120L) within a recirculating aquaculture system (RAS). Fish were fed twice daily, ad libitum, for eight weeks. Haematologic parameters, plasma metabolites, innate immune parameters, and hepatic and intestinal oxidative stress indicators were analysed.

*(Continued on next page)*

**Results**

The *in vitro* antimicrobial assays showed that extracts from CC-MM could inhibit the growth of *Lactococcus garvieae* and *Tenacibaculum maritimum*, while no inhibitory effect was observed in SMS-MM extracts. At the end of the growth trial, the increased inclusion level of MM from 12.5 to 25%, regardless of MM type, reduced lactate levels and alternative complement pathway activity and increased cholesterol levels in the plasma of juvenile rainbow trout. No significant effect was observed on plasma glucose or triglyceride levels, nor on lysozyme, peroxidase, protease, or anti-protease activities. Fish fed CC25 showed significantly higher hemoglobin levels compared to those fed the CTRL diet, while hematocrit values remained unaffected by dietary treatment. Hepatic and intestinal lipid peroxidation was also unchanged across experimental diets. Hepatic catalase activity was higher in fish fed 12.5% MM inclusion diets compared to those fed 25% inclusion diets, regardless of the MM type. Notably, fish fed the SMS diets demonstrated increased intestinal glutathione S-transferase activity. Fish fed the CTRL diet showed a significantly higher intestinal glutathione reductase activity than all other experimental treatments.

**Conclusion**

In the present study, CC-MM extracts showed antimicrobial activity, while the SMS-MM extracts showed no detectable effect. However, when included in aquafeeds, both CC-MM and SMS-MM had a similar impact on rainbow trout juveniles' immune and hepatic and intestinal oxidative status. These findings indicate that producing MM with a circular approach, using SMS, does not impair fish health. Further studies, including bacterial challenge trials, are recommended to assess the impact on disease resistance.

## Introduction

Insect meals have been extensively studied as a sustainable alternative ingredient for aquafeeds, particularly the yellow mealworm (*Tenebrio molitor*). To date, most studies have focused on defatted insect meals, which contain between 4–14% lipid content [1]. Industrial processing of insect larvae often includes defatting, a thermal-mechanical fat removal step [2], due to the high susceptibility of lipids to oxidation, which may compromise shelf-life and hinder pulverization processes. Nevertheless, the defatting process may reduce both the environmental sustainability and economic viability of insect meal production and potentially affect its functional properties [3]. Notably, mealworms have a naturally high fat content, reaching 30% [1]. This study aimed to evaluate the comparative effects of full-fat and defatted mealworm meal as alternative feed ingredients to fishmeal, on growth performances, whole-body composition, fillet fatty acid profile, and quality attributes of rainbow trout (*Oncorhynchus mykiss*).

## Materials and methods

A single batch of mealworm larvae was either subjected or not subjected to a thermos-mechanical defatting process, resulting in two distinct mealworm meals (MM): a full-fat mealworm meal (FFMM, crude protein: 51.9%, crude lipids: 32.8%) and a defatted mealworm meal (DMM, crude protein: 66.7%, crude lipids: 12.9%). Three isoproteic (45%) and isolipidic (22%) experimental diets were formulated for juvenile rainbow trout. A control diet (CTRL) was formulated to mimic the composition of a conventional commercial trout diet. Two other diets were formulated based on the CTRL diet but incorporated 25% of the full-fat and defatted MMs, totally replacing fishmeal (FFMM and DMM diets). All diets included 11.5% of fish oil (dry matter basis), and rapeseed oil was adjusted to maintain consistent lipid levels across all formulations. A growth trial was conducted with juvenile rainbow trout (11.4 ± 1.5 g). Nine homogeneous groups of 20 fish each were randomly assigned to nine fiberglass tanks (120L), within a recirculating aquaculture system kept at a constant 14 °C. Fish were fed to apparent satiation, twice daily, over an eight-week period. At the end of the trial, zootechnical parameters, whole-body composition, and fillet quality and composition were evaluated.

Table 1 - Muscle fatty acid composition of the rainbow trout fed the experimental diets

| Fatty acids (% fatty acids) | CTRL | FFMM | DMM | PSEM | ANOVA |
|---|---|---|---|---|---|
| SFA | 21.3 $^{a}$ | 25.4 $^{b}$ | 21.9 $^{a}$ | *0.68* | < 0.001 |
| MUFA | 39.0 $^{b}$ | 35.8 $^{a}$ | 38.6 $^{b}$ | *0.55* | 0.005 |
| PUFA | 37.4 | 36.1 | 37.1 | *0.27* | ns |
| n-3 | 22.4 $^{c}$ | 16.9 $^{a}$ | 20.1 $^{b}$ | *0.80* | < 0.001 |
| n-6 | 14.1 $^{a}$ | 18.4 $^{c}$ | 16.3 $^{b}$ | *0.63* | < 0.001 |

SFA: Saturated fatty acids; MUFA: Monounsaturated fatty acids; PUFA: Polyunsaturated fatty acids. n-3: n-3 PUFA; n-6: n-6 PUFA. Values are presented as mean and pooled standard error of the mean (PSEM). Superscript letters indicate significant differences ($p < 0.05$) between the experimental treatments

*(Continued on next page)*

**Results**

At the end of the feeding trial, rainbow trout exhibit an eightfold increase in body weight, with no significant difference observed in overall zootechnical parameters across dietary treatments. However, both the FFMM and DMM diets led to a reduction in feed intake, while simultaneously improving feed efficiency. Furthermore, the hepatosomatic index was significantly lower in fish fed the FFMM diet compared to fish fed the CTRL diet. Whole-body dry matter and protein contents were unaffected by experimental diet. In contrast, lipid content was significantly higher in fish fed the DMM than in those fed the CTRL diet. Additionally, whole-body energy and ash contents were significantly elevated in fish from both the FFMM and DMM groups relative to the CTRL group. In the fillet, no significant differences were observed in dry matter and protein contents, among the dietary treatments. However, fillet lipid content was higher in the FFMM group compared to the DMM group. No differences were observed in muscle lipid peroxidation, pH, or textural parameters (hardness, adhesiveness, springiness, cohesiveness, chewiness, and resilience). Colorimetric analysis showed higher b* values in the CTRL and FFMM groups compared to those from the DMM group, indicating a more yellow coloration in the former treatments. The fillet fatty acid class profile is summarized in Table 1. SFA and MUFA contents were higher in the FFMM groups compared to both the CTRL and DTM groups. The CTRL diet led to the highest concentrations of n-3 PUFA and the lowest n-6 PUFA contents, followed by DMM and FFMM diets. Consequently, fish fed the FFMM diet exhibited higher atherogenicity and thrombogenicity indexes, whereas fish from the CTRL and DTM groups demonstrated higher hypocholesterolemic / hypercholesterolemic ratios and peroxidation indexes

**Conclusion**

Overall, the defatted mealworm meal promoted a more favourable fatty acid profile, with higher n-3 and n-3/n-6 ratio, and more beneficial health-related lipid indices. These results suggest that defatted mealworm meal may be a more suitable replacement for fishmeal. However, the use of full-fat mealworm meal could also be considered to reduce the need for added vegetable oils.

**Introduction**

Swimming is a fundamental behavioural element that contributes to fitness in most fish species. Promoting swimming activity in aquaculture has emerged as a strategy to enhance fish welfare and physiological resilience, particularly in flow-based systems on land, such as raceways [1]. Controlled swimming has been shown to modulate the stress axis and boost immune competence [2]. Still, the physiological outcomes depend strongly on exercise intensity and pattern, and varies greatly across species. This study investigated the short-term effects of different swimming regimes on stress response, innate immune system and antioxidant status in juvenile rainbow trout (*Oncorhynchus mykiss*), using a standardized individual flume setup.

**Materials and methods**

Thirty-two fish (body length (BL): 13.0 ± 0.2 cm) were individually induced to swim in acrylic swimming flumes for 6 hours to one of four experimental conditions: minimal water flow (control, < 0.1 $BL \cdot s^{-1}$); low-speed (L, 0.8 $BL \cdot s^{-1}$); high-speed (H, 2.3 $BL \cdot s^{-1}$); and oscillating speeds (O, 0.8/2.3 $BL \cdot s^{-1}$); n = 8. Immediately after the trials, fish were anaesthetised with MS-222 (0.1 $g \cdot L^{-1}$) and subsequently euthanised. Skin mucus was collected by carefully scraping the dorso-lateral surface of the fish [3]. Blood samples were collected immediately with heparinised syringes via the caudal puncture. The blood was centrifuged (10,000 × *g*, 5 min, 4 °C) to obtain plasma. Cortisol, glucose and lactate levels were determined in plasma, while lysozyme, peroxidase, protease and antiprotease activities were measured in both plasma and skin mucus [4]. Liver and red and white skeletal muscle were dissected for oxidative stress biomarkers [5]. Data were analysed by one-way ANOVA to determine differences between groups. The level of significance used was $P < 0.05$ for all statistical analyses.

**Results and discussion**

Rainbow trout induced to swim for 6 h in L, H, or O conditions exhibited significantly lower plasma cortisol levels compared to the non-swimming control group, indicating a reduced neuroendocrine stress response. This aligns with earlier findings in salmonids suggesting that induced swimming activity generates a decrease in cortisol release [2].

While no significant alterations were detected in plasma immune markers, skin mucus samples revealed enhanced innate immunity, as shown by elevated lysozyme and peroxidase activities in fish from the L and H groups. These enzymes are key components of the first-line mucosal defence and their up-regulation may reflect localized immune stimulation.

Red and white muscle tissues from fish in L and H conditions displayed improved redox status, with an increased reduced/oxidized glutathione ratio, suggesting enhanced antioxidant defences and improved cellular protection against reactive oxygen species (ROS). This redox shift may represent a physiological adaptation to moderate swimming-induced aerobic metabolism. In contrast, the O group showed elevated lipid peroxidation in liver, indicative of oxidative damage. The unsteady nature of oscillating flows may increase metabolic fluctuation and ROS production, thereby overwhelming hepatic antioxidant capacity. These contrasting outcomes across induced swimming conditions highlight the importance of applying the most favourable water flow towards optimisation of physiological responses.

*(Continued on next page)*

Overall, the findings support the hypothesis that induced swimming can activate beneficial physiological responses in a context-dependent manner, with outcomes varying by tissue type and swimming regime.

**Conclusion**

These findings highlight the potential of short-term induced swimming to modulate stress, immune, and redox responses in rainbow trout. Enhanced mucosal defence and antioxidant status, combined with reduced cortisol levels in plasma, suggest that controlled swimming may serve as a useful strategy to improve fish resilience before stressful aquaculture procedures such as handling or transport. However, the observed oxidative stress in fish under oscillating conditions underscores the need for careful protocol design. Further research under group settings and longer durations is needed to assess the long-term implications of these responses in production environments.

Havneveien 6
N-8700 Nesna, Norway
Email: dagfinn.stromme@zoetis.com
Email: hanne.andersen@zoetis.com

Injection vaccines are quickly becoming the method of choice for farmed fish species kept in high densities, mainly due to the long-term protection they provide for the fish. In order to ensure proper immunization, animal welfare, and sustainability, it is important that the vaccinations are done accurately, gently and swiftly.

Today the majority of fish are vaccinated by hand, but vaccination by machine is becoming increasingly more common in salmon, trout, sea bass, and tilapia farming. Current manual injectors can inject one or two vaccines intraperitoneally or intramuscularly, but it is not possible to inject in two different locations simultaneously.

Delivering vaccines accurately and gently requires skill, and in many regions, there is a shortage of trained personnel. Machine vaccination offers a way to maintain consistency and precision, even when human resources are limited.

We will present the use of injection tools to enable vaccinations of large numbers of fish, while increasing production efficiency, improving sustainability, and maintaining a high level of fish health. We will also touch on emerging opportunities made possible by new technologies. One of the most promising is image-based data capture — vaccination day is often the only time each fish is individually handled. Could that moment also be used to gather meaningful information about the fish and its health status with the aid of Artificial Intelligence?

# AI QUANTIFICATION OF ATLANTIC SALMON BEHAVIOR FROM SINGLE POINT VIDEO TRAINED WITH AUTO LABELED SYNTHTIC DATA

Marius Andersen*

SINTEF Ocean
P.O. 4762 Torgarden

E-mail: marius.e.andersen@sintef.no

## Introduction

The problem of segmentation and pose prediction of animals in images is still a significant challenge. Part of the difficulty lies in the complexity, accuracy and volume of training data required. This work presents a novel method for creating synthetic training data. This data is used to train a convolutional neural network that can analyze salmon behavior in consecutive frames. The use of synthetic data solves the problem of data amount and accuracy and allows for model evaluation with a known ground truth.

## Synthetic training data

The synthetic training data is primarily created by manipulating a single 3D model of a salmon. This 3D model is copied and given random poses within the view cone of a virtual camera along with some light sources. The image of the salmon instances is rendered and combined with a randomized gradient background. The image is completed by adding some random noise and a soft Gaussian blur. This process is illustrated in Figure 1. An arbitrary number of randomized images can then be created using this process.

The use of a known 3D object also allows for attaching key points to the model mesh. These key points can then be used to train a pose prediction model like YOLO11 pose. The model along with the key points representing a simple fish spine is shown in Figure 2.

## Initial AI model results

The synthetic training data has been used to train a YOLO11 instance segmentation model that has never seen a real salmon. The initial results from this training are promising, as can be seen in Figure 3, where the trained model is evaluated on a real video capture of salmon. This initial model can produce serviceable masks for the same individual over several frames. The positive results have prompted further research into pose estimation of salmon using key points. Research on pose estimation is currently in the works and will be further elaborated on.

# EFFECTS OF CO-FARMING RAINBOW TROUT (*Oncorhynchus mykiss*) AND DUCKWEED (*Lemna minor*) ON NITROGEN CYCLING AND FISH HEALTH IN RAS

M. Andersson*, P. Dittmer, R. de Fonseka, D. Doyle, J. A. C. Roques and K. Sundell

**Background**

Co-farming within integrated multitrophic aquaculture (IMTA) can improve the nutrient retention and utilization in aquaculture. In IMTA systems, the nutrients from fed species are consumed by extractive species, thereby converting waste products into new biomass. Duckweed (*Lemna minor*) is a freshwater plant that has been suggested as an efficient nitrogen and phosphate remediator in aquaponics and Recirculating Aquaculture Systems (RAS). The high growth rate in combination with an ability to assimilate nitrogen from both ammonia, nitrite, and nitrate, makes it a suitable for co-farming with fish. In warm-water RAS, duckweed has been found to reduce ammonia concentrations in the water and improve fish growth. There is, however, a lack of studies on the potential effects of using duckweed as an extractive species in cold-water RAS.

On the Swedish west coast, RAS are expected to be the main system for future aquaculture expansion due to strict environmental laws in combination with coastal waters in risk of eutrophication. To achieve a high degree of water recirculation in RAS, there is a need for efficient methods to utilize the dissolved nitrogenous waste. Co-farming with duckweed is a potential solution to extract the nitrogens and thereby improve system water quality. As the main farmed fish species in Sweden is rainbow trout (*Oncorhynchus mykiss*) in cold freshwater, duckweed can be added on as an extractive species without altering the preferred water parameters. The research question in this study was to evaluate the effects on water quality and system nitrogen as well as growth, health, and welfare of rainbow trout when co-farmed with duckweed. To assess this question, we performed a 6-week co-farming trial in two identical RAS systems except that one system held only fish and the other held both fish and duckweed that were farmed in a separate rack system connected in parallel to the RAS.

**Material and methods**

Two identical freshwater RAS (425 L) were set-up in a temperature control room (water temperature 12.2 °C), each containing four aquaria (93.2 L). The RAS loop contained two mechanical filters, a pump sump with a biofilter of bio balls, a UV-filter, and air bubbling. At the experimental start 72 rainbow trout, with an average mass of 47.5 ± 0.86 g (± SEM), were added to each system. One of the RAS also had a rack with four duckweed tanks (23 L) attached in the loop, with LED lights above each tank. At the experimental start, 186 g duckweed was distributed between the holding tanks. The experiment lasted for 6 weeks.

Water samples were taken three times per week to analyse for dissolved ammonium ($NH_4^+$), nitrite ($NO_2^-$), nitrate ($NO_3^-$), and phosphate ($PO_4^{2-}$). Dissolved inorganic nitrogen (DIN) was calculated as the sum of $NH_4^+$, $NO_2^-$, and $NO_3^-$. The mass of feed given to the fish was registered for each day and system and remaining feed pellets and faeces were collected and separated. The pellets and faeces were dried and weighted and sent for analysis of total nitrogen content. Duckweed was harvested when required, based on their density, and the removed biomass was weighted and sent for analysis of total nitrogen content. Selected observational welfare indicators (OWIs) were recorded for all fish triweekly, and each tank was scored for presence (1) or absence (0) of the following four OWI parameters: skin haemorrhage, scale loss, snout wound, and eye damage.

At the final sampling, fish (n = 12) were euthanized in metomidate (12 mg/L) and killed with a sharp blow to the head. A blood sample was taken from the caudal vein, centrifuged, and the plasma was stored in -80 °C for subsequent analysis of cortisol and ion concentrations. Samples of skin, proximal intestine, and distal intestine were taken for *in vitro* analysis of barrier function using the Ussing chamber technique. Liver samples were taken and placed in liquid nitrogen until analysed for two oxidative stress markers: lipid peroxidation (LPO) and glutathione assay.

*(Continued on next page)*

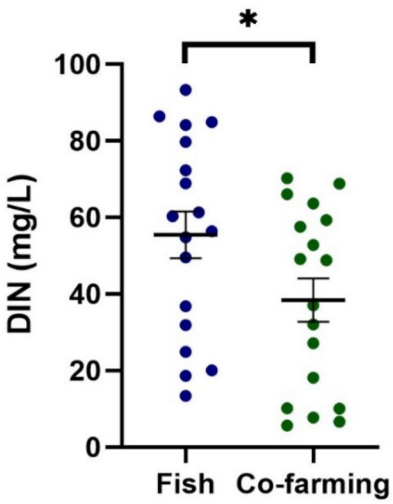

**Figure 1.** The DIN concentrations in the two s
ystems throughout the study.

| Welfare indicator | Fish | Co-farming |
|---|---|---|
| Skin hemorrhage | 0 | 0 |
| Scale loss | 70,6 | 55,9 |
| Snout wound | 70,6 | 60,3 |
| Eye damage | 2,9 | 2,9 |

**Table 1**. Score of observational welfare indicators (%).
farming system.

**Results and discussion**

DIN concentrations in the co-farming system (38.3 ± 5.5 mg/L) were lower than in the system with only fish (55.4 ± 5.9 mg/L; $t(34) = 2.049$, $p = 0.048$). This reduction was reflected in lower concentrations of $NO_3^-$ and $NO_2^-$ but not $NH_4^+$. The dissolved nitrogen was mainly present as $NO_3^-$ (54.45 ± 5.90 mg/L for fish, 37.27 ± 5.49 for co-farming) with less as $NO_2^-$ (0.59 ± 0.04 mg/L and 0.38 ± 0.04, respectively) and even less as $NH_4^+$ (0.37 ± 0.03 mg/L and 0.69 ± 0.07, respectively). This suggests that the duckweed was an efficient assimilator mainly of $NO_3^-$ and $NO_2^-$ in our system. The $PO_4^{2-}$ concentration tended to be lower, although not statistically significant, in the co-farming system (6.53 ± 1.86 mg/L) than the fish system (6.83 ± 0.80 mg/L).

The pH was higher for the co-farming system (7.24 ± 0.07) than the system with only fish (6.95 ± 0.11; $t(34) = -2.183$, $p = 0.036$). Maintaining a high pH in RAS is a challenge as it tends to be reduced by $CO_2$ production of fish and microbes at the same time as the alkalinity is consumed by nitrifying bacteria in the biofilter. The results suggest that co-farming with duckweed could help counteract these effects.

There were no growth differences of the rainbow trout between the two systems. The welfare indicators scale loss and snout wound, although not statistically significant, tended to be less frequently occurring in the co-farming system.

At the conference, remaining effects on fish health and welfare will be presented, including plasma cortisol and ion concentrations, skin and gut barrier function, and oxidative stress markers in the liver tissue.

# ACCESSIBLE DEPOSITION MODELLING TOOLS FOR IMPROVED ENVIRONMENTAL PLANNING (ADEPOPLAN)

Birgitta Andreasen*, Sissal V. Erenbjerg, Gunnvør á Norði, Pål N. Sævik, Esbern J. Patursson, and Jan H. Egholm

Firum
við Áir 11
FO-430 Hvalvík, Faroe Islands
Email: birgitta@firum.fo

The overall objective of the ADepoPlan project is to improve the environmental planning toolbox available for the Faroese environment, for both industry and government, by making validated deposition models more accessible to stakeholders with limited modelling and programming experience.

As salmon aquaculture in the Faroe Islands continues to grow and expand into more exposed environments, accurate predictions of particulate organic matter (POM) deposition footprints, for both non-dispersive and dispersive fish farms, are essential for both sustainable management and regulatory compliance.

To address the need for accessible deposition models, we have developed a user-friendly prototype application that integrates the open-source Lagrangian Advection and Diffusion Model (LADiM) with 3D hydrodynamic forcing data from the FarCoast hindcast archive, developed at Firum. This R Shiny-based application incorporates a combination of Python and R code, ensuring ease of use while maintaining model flexibility. The app facilitates the integration of high-resolution oceanographic data, allowing users to simulate and predict POM deposition with minimal technical expertise. The application will be open-source at the end of the project for everyone to use and to generate trust in the model output by promoting transparency and reproducibility.

The prototype can enhance decision-making by improving site selection, impact assessments, and adaptive management strategies. Additionally, it strengthens environmental monitoring by identifying optimal locations for sediment sampling, allowing for more targeted and effective monitoring programs.

By making advanced deposition models more accessible, the ADepoPlan project strengthens environmental management of aquaculture and supports sustainable marine resource use.

# INFLUENCE OF LIGHT AND TEMPERATURE ON MATURATION AND REPRODUCTIVE SUCCESS IN *Hediste diversicolor*

Inka Anglade[1]*, Frida Espejord[2], Synne Spjelkavik[1], Kjell Inge Reitan[2], Andreas Hagemann[1]

## Introduction

Sustainable growth of the salmon aquaculture industry is highly dependent on the availability of new and locally produced feed resources (Albrektsen et al., 2022, Tacon et al., 2011), and improved approaches to managing and utilizing waste streams from production (Waite et al., 2014, Turchini et al., 2019). Polychaetes can upcycle valuable biomolecules contained in aquaculture sludge and other waste streams (Anglade et al., 2023, Wang et al., 2019a), while at the same time being a potential feed ingredient in aquafeeds (Monteiro et al., 2024, Wang et al., 2019b). Future large-scale production of the polychaete *Hediste diversicolor* (OF Müller, 1776) will be dependent on extensive knowledge, control, and manipulation of the life cycle of the species (Olive, 1999, Wang, 2020). In this study, the effect of different light and temperature regimes on the maturation and reproductive success of *H. diversicolor* was evaluated.

## Material and methods

Wild collected individuals of *H. diversicolor* were acclimated under laboratory conditions for two months prior to being transferred to the experimental units in December 2024. A full-factorial experimental design was used, combining two temperature regimes (14°C and a temperature regime of 6-14°C simulating natural temperature variation) with four light regimes (16L:8D, 24L:0D, natural light conditions, accelerated natural light conditions), resulting in seven treatment combinations. Each treatment consisted of four experimental tanks and one reference tank. All groups were fed commercial fish feed twice weekly. In the reference tanks, biweekly sampling was conducted to assess survival, measure individual biomass, document individual condition via photographic analysis, and assess maturation status by extraction of germ cells from a minimum of five individuals per sampling.

After 14 weeks, all remaining were dissected to quantify reproductive output in females through egg counts. At the same time, an exploratory sampling was conducted in the experimental tanks to determine the presence or absence of offspring, with the aim of verifying spawning and reproductive success. Additionally, more comprehensive samplings were scheduled for weeks 20 and 26 to assess later developmental stages and further evaluate reproductive success across treatments.

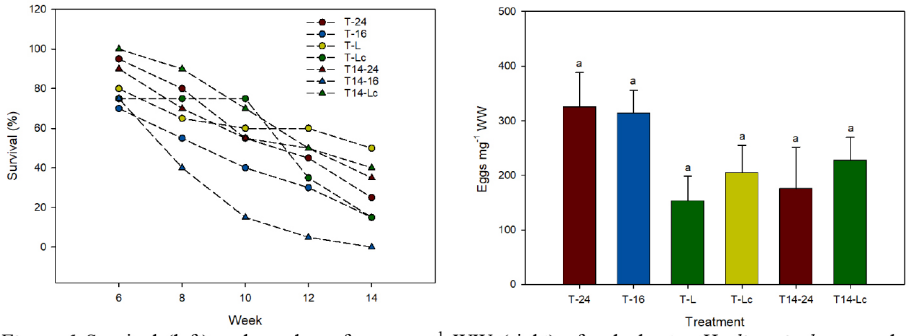

*Figure 1* Survival (left) and number of eggs mg$^{-1}$ WW (right) of polychaetes *H. diversicolor* reared under different light and temperature regimes over a 14 week-period. Same superscripts indicate non-significant differences ($p \geq 0.05$).

*(Continued on next page)*

**Preliminary results and discussion**

With the progression of maturation, the survival of *H. diversicolor* decreased across all treatments over time due to its semelparous life history (Hartmann-Schröder et al., 1996). Individuals in the 16L:8D light treatment group, in both natural temperature conditions and at 14°C showed the most rapid decline in survival. Correlating this decline with the onset of reproduction and higher reproductive success in terms of offspring numbers will be crucial for understanding these results, however, this is yet to be evaluated. Variation and light did not affect the final egg $mg^{-1}$ count (one-way ANOVA, $p \geq 0.05$), suggesting no difference in retention of eggs in the coelom.

**Conclusion**

Overall, the light regime appeared to exert a stronger influence on the maturation of *H. diversicolor* than temperature, with more detailed results yet to be assessed. These findings may support the development of large-scale production systems by enabling faster maturation and reproduction.

# EVOLUTIONARY AND FUNCTIONAL INSIGHTS INTO THE BITTER TASTE SYSTEM OF GILTHEAD SEABREAM (*Sparus aurata*): LINKS TO GUT SENSING AND FEEDING REGULATION

Rita Angotzi*, Elisa Sanchez, Borja Muriach, Alicia Benítez and José Miguel Cerdá Reverter

Fish NeuroBehaviour Lab, Department of Fish Physiology and Biotechnology
Instituto de Acuicultura de Torre de la Sal, IATS-CSIC
Torre la Sal s/n, Ribera de Cabanes

Email: rita.angotzi@iats.csic.es

**Introduction**

Improving feed palatability is a key priority in sustainable aquaculture especially considering the progressive incorporation of alternative ingredients in aquafeeds. These components contain a variety of anti-nutritional factors (ANFs), often associated with a bitter taste, along with adverse effects on fish growth [1]. Bitter tastes are signaled by a GPCR family member, known as type 2 taste receptors (T2Rs) [2]. Despite recent advancements in genomic and functional studies revealing the diversity and roles of T2Rs across a wide range of vertebrates [3], key aspects of T2R biology in aquaculture-relevant species remain underexplored. Understanding bitter functions in this context is especially relevant, as studies in mammals have shown that beyond oral taste, T2Rs can modulate hormones secretion from enteroendocrine (EE) cells, thereby influencing feed intake via the gut-brain axis [4]. In light of these knowledge gaps, this study aimed to characterize the T2R gene repertoire from evolutionary and functional perspectives in the gilthead seabream (*Sparus aurata, sa*), with a particular focus on their potential role as chemosensors for specific ANFs, commonly found in plant-based aquafeeds. Lastly, we search evidence for mRNAs co-expression of *sa*T2R with a subset of anorexigenic EE-peptides, to provide morphological evidences of the potential conserved roles for fish T2Rs in GI-sensing mechanisms regulating appetite and digestion.

**Material and Methods**

Novel fish T2Rs sequences were identified through BLAST/BLAT searches against representative fish genome assemblies (Ensembl, release 111, 2024), using NCBI-annotated teleost T2R protein as queries. A curated dataset (n=125) was then used for phylogenetic reconstructions in MEGA11 [5]. T2R synteny was manually assessed using the Ensembl BLAST MultiTool. *In vitro* responses to known bitter ligands and ANFs were assessed by transiently transfecting the bitter family member *sa*T2R-40 (in pcDNA3) into the stable NFAT-Luc-HEK293 cell line, to drive $Ca^{2+}$-dependent luciferase expression upon receptor activation [6]. Evaluation of ligand responses was based on relative luminescent unit (RLU) mean ± SEM of 8 independent determinations normalized to the mean response of basal levels (% BL). Dual fluorescent *in situ* hybridization (DFISH) was performed using DIG- and fluorescein-labelled riboprobes for *sa*T2R-40, the EEC marker ND1, and the cholecystokinin (CCK) and proglucagon (Pg) genes. Fluorescent signals were developed as previously described [7].

**Results**

BLAST-based gene mining in genome assemblies identified five *sa*T2R paralogs, located on chromosomes 5 (*sa*T2R-40/*sa*T2Rb) and 9 (*sa*T2Rc/d/e), belonging to three distinct phylogenetic clades. Analyses of *sa*T2R syntenic blocks with both closely and distantly related species (including non-teleosts and lobe-finned fish) indicate frequent rearrangements, duplications, and losses across lineages and suggest that *sa*T2R-40/b/e are ancestral gene- paralogs that originated before the tetrapod/ray-finned fish divergence (**Fig.1**), whereas *sa*T2Rc/d most likely arose from whole-genome or segmental duplications at the basis of teleost radiation. Stimulation of *sa*T2R-40-transfected NFAT-Luc-HEK293 cells with the canonical bitter ligand denatonium, as well as with the ANFs genistein and saponin, elicited significant responses that tended to increase in a dose-dependent manner (**Fig.2**). The $Ca^{2+}$ release activator Phorbol 12-myristate 13-acetate (PMA), served as positive control. DFISH experiments provided clear indications for the colocalization of *sa*T2R-40 with the EEC-peptides CCK and Pg (**Fig.3**), supporting the hypothesis that *sa*T2R-sensing in EECs play a central role in the release of anorectic hormones in response to ANFs.

Fig.1

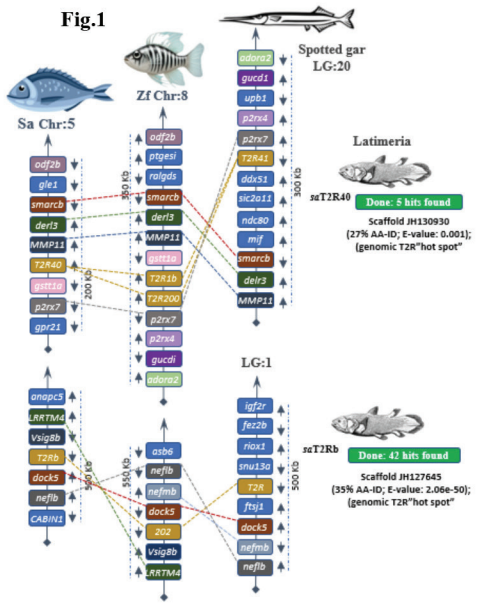

Fig.2

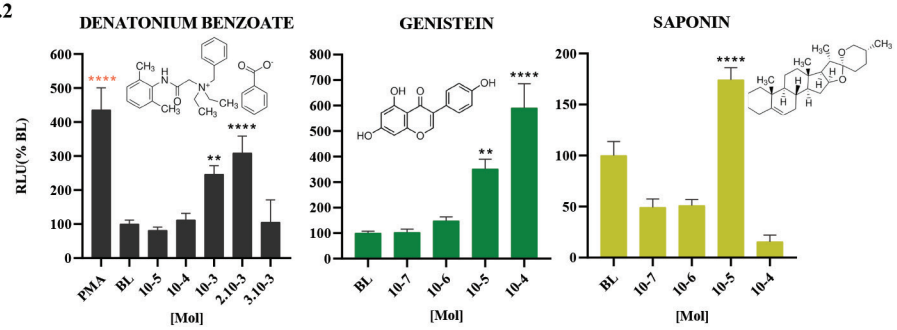

Fig.3

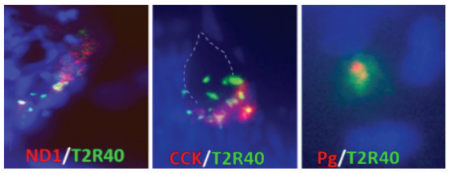

## Conclusions

Globally, these studies provide foundational knowledge that sheds light on the evolutionary and functional aspects of T2R biology, with important implications for applied aquaculture. Beyond their impact on feed palatability, the data support the hypothesis that the detrimental effects of ANFs on fish growth may be mediated, at least in part, by T2R- signalling in the GI tract. This information is instrumental for testing, *in vitro*, potential bitter-masking compounds that could ultimately contribute to the design of novel alternative feed formulations capable of mitigating the release of appetite-suppressing signals from the gut, thereby enhancing feed intake and reducing the environmental impact of feed waste.

*E-mail: catarina.anjos@necton.pt

Microalgae play a key role in aquatic ecosystems and are also crucial for the aquaculture sector, particularly during the early life stages in hatcheries (1,2). The use of microalgal biomass supplied by specialized companies, in the form of pastes, concentrates, or powder, has become a practical strategy, offering consistent biomass availability while reducing the risk of microalgae culture crashes that often occur with on-site production (3). It also optimizes space and labour, allowing hatchery staff to focus on the growth and health of their target animals. Therefore, the use of commercial microalgae products is well established in fish hatcheries. However, their adoption in the invertebrate aquaculture sector remains limited, even though most of these organisms rely on algae throughout their entire life cycle. One possible reason is that their specific nutritional requirements differ according to the life stage (larvae, juveniles, adults, and broodstock) and species. In addition, commercial microalgae genera such as *Nannochloropsis* sp., *Tetraselmis* sp. and *Tisochrysis* sp. may not fully meet those needs (3). For this reason, it is essential to investigate other marine microalgae, such as diatoms, as they have been shown to play a crucial role in the nutrition of invertebrates such as bivalves, shrimp, sea cucumber, and sea urchin. Additionally, innovative diets are being investigated as research showed that the inclusion of diatoms as a functional ingredient presented relevant biological benefits, such as immunostimulation (4). One of the first steps in industrial microalgae production is the establishment of species-specific cultivation protocols to enable consistent and scalable biomass production. As part of the Algae Vertical project, production of four diatom species (*Chaetoceros calcitrans, Phaeodactylum tricornutum, Thalassiosira pseudonana* and *Skeletonema costatum*) was performed to characterize their growth performance and biomass productivity. Trials were carried out at an industrial microalgae production facility in southern Portugal under natural outdoor conditions. Most species were cultivated in winter (November-February), except *C. calcitrans,* which was produced during summer (July–August). Cultivations were performed in flat-panel photobioreactors (FP-PBR) along different culture volumes (80–3000L), by transferring the cultures from the smallest systems to the largest, or by splitting the cultures in several reactors of the same volume, to scale up the production. NutriBloom® Plus medium and NutriBloom® Silicates solutions were applied to maintain nitrate and silicate concentrations of 4 mM and 1 mM, respectively, except for *P. tricornuturm*, where only NutriBloom® Plus was used. The growth of the microalgae was monitored through daily optical density measurements. At the end of the production cycle, biomass was harvested by centrifugation, and the yield of the fresh paste was recorded. Following harvesting, biomass was packed and immediately frozen at -20°C for downstream processing (e.g. lyophilization or product formulation). All four diatoms were well adapted to outdoor cultivation in FP-PBR in southern Portugal (Figure 1). *C. calcitrans* reached a productivity of 0.248 $g.L^{-1}.d^{-1}$ within 13 days in 80L, while a slower growth was observed in a 3000L reactor. *T. pseudonana* showed consistent performance across all cultivation volumes, with a maximum productivity also reaching 0.255 $g.L^{-1}.d^{-1}$. *P. tricornutum* exhibited rapid initial growth at 80L, reaching 0.154 $g.L^{-1}.d^{-1}$ productivity, though larger volumes showed a more gradual microalgae growth. *S. costatum* maintained a stable growth at 1000L replicates, with a maximum productivity of 0.244 $g.L^{-1}.d^{-1}$. This work demonstrates the feasibility of producing different diatom species at a pilot scale in an industrial production setting. This represents a step toward the development of new commercial products of microalgae to meet the nutritional requirements of aquatic organisms, particularly for bivalves and other invertebrates. However, to complete the process of microalgae product formulation, further efforts should focus on the biomass harvesting and post-processing steps (e.g. storage and lyophilization). Some of these challenges include damaged *setae* in *C. calcitrans* and colour changes in *S. costatum* and *P. tricornutum* biomass during harvesting or the storage period. These aspects must be addressed to reach a high-quality product for aquaculture applications.

# EFFECT OF THERMAL TREATMENT ON THE SHELF-LIFE OF MICROALGAE LIQUID CONCENTRATES WITH DIFFERENT BIOMASS DRY WEIGHTS FOR HATCHERY APPLICATIONS

C. Anjos[1*], G. Bastos[1,2], A. Rodrigues[1], J. Navalho[1], and P. Diogo[1]

[1]Necton, S.A., Belamandil, 8700-152 Olhão, Portugal

*E-mail: catarina.anjos@necton.pt

Microalgae product innovation is essential to improve aquaculture production efficiency, which is crucial for meeting the increasing global demand for fish for human consumption. One of the main challenges lies in reducing the bacterial content in microalgae-based products, as their presence increases the bacterial load and communities in the water of rotifer culture, potentially enhancing the probability of pathologies and outbreaks. This is particularly concerning for marine fish larvae, which are often sensitive to bacterial presence. Commercial liquid concentrates of microalgae tend to carry significant bacterial loads, threatening larvae survival by increasing the microbial population in both rotifer and larvae rearing systems (1–3). The application of thermal treatments in microalgae liquid concentrates has previously shown microbiological benefits (1), but it can induce agglomeration of the product. This creates an additional challenge in the development of microalgae products with reduced bacterial loads, for instance, for recirculating aquaculture systems (RAS) and the green water technique. RAS are very efficient culture systems; however, most microalgae products cannot be applied in these tanks since the presence of microalgae agglomerates clogs the filters, impairing their application in these systems (3). In the green water technique, these agglomerates tend to foster product sedimentation, reducing the water quality and biological efficiency of the fish larvae. Product formulation factors such as salinity, microalgal dry weight and thermal disinfection influence product quality. It is known that different biomass dry weights affect microalgae agglomeration and product sedimentation, which may reduce the water quality and feed availability for the organisms, ultimately impacting their biological performance. This study investigates the effect of low-temperature long-time (LTLT) thermal treatment on *Nannochloropsis* sp. liquid concentrates formulated at different dry weights (8%, 15%, and 18%) under constant salinity, compared to untreated samples (Control). After formulation, the products were frozen and, following one month of storage, thawed and monitored weekly over a four-week refrigerated storage period (secondary shelf life). During this period, product sedimentation in the water column (after 24h) and microbiological parameters (Tryptic Soy Agar - TSA; Plate Count Agar – PCA; and Thiosulfate Citrate Bile Salts Sucrose Agar - TCBS) were assessed. Figure 1 shows the total bacterial content growth in TSA in samples with 8%, 15%, and 18% dry weight under control and LTLT treatment over 0, 1, and 4 weeks.

Bacterial content increased across all liquid concentrates with different biomass dry weights during the storage period. At the end of secondary shelf life (4 weeks refrigerated), control samples consistently showed the highest bacterial loads, particularly at 15% and 18% dry weights. In contrast, LTLT samples showed lower microbial growth at all time points, especially at 15% dry weight, confirming the efficacy of LTLT in reducing microbial growth. These results are in agreement with previous studies, which showed that thermal treatment reduces bacterial load in microalgae concentrates (1). Sedimentation tended to decrease over time; the control samples showed higher pellet heights than LTLT, suggesting that thermal treatment may reduce the aggregation and settling capacity of the biomass, which is beneficial for these product applications in the hatchery. These findings suggest that thermal treatment is a promising strategy to improve the microbiological and physical stability of microalgae concentrates used in aquaculture. From a practical standpoint, this thermal processing approach can extend the secondary shelf life of microalgae-based products due to the reduced bacterial levels and lower product sedimentation, which are key requirements for sensitive aquaculture species and challenging aquaculture systems. Nevertheless, *in vivo* trials in rotifers and fish larvae are needed to validate the biological efficacy of these products under industrial aquaculture conditions. This research supports the development of safer and more stable microalgae-based products that not only meet the organisms' biological needs but also align with operational constraints in modern fish hatchery facilities.

*Email: larantzamendi@azti.es

**Background**
Bivalve aquaculture has been identified as a key sector for the sustainable growth of aquaculture in Europe. However, the reported benefits of bivalve aquaculture for the environment and potential environmental risks have not been well-defined or quantified, and the risk-benefit trade-off remains unclear.

**Methodology and aims**
Firstly, the study aims to detail the positive contributions of bivalve aquaculture in the EU in addressing biodiversity loss, pollution, and climate change (including mitigation efforts), while also considering any possible negative impacts on ecosystems through a systematic literature review. Secondly, a consultation with bivalve aquaculture stakeholders (across several MS) was conducted to develop a SWOT analysis of the current environmental, economic, social, regulatory/institutional, and technological aspects. This analysis seeks to identify opportunities for growth of the bivalve aquaculture by implementing the identified environmental benefits and considering the impacts, focusing on the challenges and opportunities in promoting the benefits of bivalve aquaculture.

The literature review analysis was based on a systematic literature review (SLR) following PSALSAR (Protocol and Reporting result with Search, Appraisal, Synthesis, and Analysis Framework). The project aimed to answer questions regarding the relationship between the bivalve farming sector with key environmental aspects, focusing on the benefits related to biodiversity, pollution and climate change, but also identifying the challenges. Web of Science, Scopus and Google Scholar databases were used. The search was restricted to research items published between 2014 and 2024, using keyword search strings such as “aquaculture AND bivalve”, “farming AND bivalve”, “aquaculture OR farming AND bivalve” and “aquaculture OR farming AND bivalve AND environmental AND benefits” and combinations with “Biodiversity”, “Pollution” and “Climate Change”.

**Preliminary results**
In total, 112 items were selected and after the full text review, 41 research items were finally selected as relevant for this study. These papers were reviewed and summarised as part of the report in order to assess the ecosystem services and related environmental benefits of the bivalve sector. Data collected through the stakeholder consultation was reviewed and critically assessed, and further insights were extracted.

**Conclusion & Outlook**
This study falls under a broader study requested by the European Commission on *Assessing the environmental benefits of aquaculture and challenges and opportunities in promoting those benefits*. The abstract and presentation focuses on the contextual background and project methodological approach, and presentation of results to inform the current state of knowledge of the environmental benefits of bivalve mollusc farming, outlining possible opportunities for development of this type of farming as a low impact type of aquaculture.

# LOW TROPHIC AQUACULTURE INFRASTRUCTURES AS NATURE BASED SOLUTIONS: ESTABLISHING FRAMEWORKS AND SUSTAINABLE AQUACULTURE PRACTICES

L. Arantzamendi*, M. Andrés, Mª J. Suárez, M. Aguinaga

AZTI
Marine Research
Basque Research and Technology Alliance (BRTA)
Herrera Kaia. Portualdea z/g
20110 Pasaia; Gipuzkoa, Spain
*Email: larantzamendi@azti.es

**Background**

Low trophic aquaculture, including species like bivalves and seaweed, offers a promising opportunity for a sustainable expansion of the global aquaculture while delivering valuable ecosystem goods and services. The EU BIOGEARS project demonstrated that biobased aquaculture gears (ropes) are a more sustainable in aquaculture production than conventional fossil-based options, helping to reduce plastic pollution in suspended bivalve culture through the circular economy. This study aims to evaluate the performance of new biobased ropes with proved mechanical properties, in low trophic mussel and seaweed aquaculture within hybrid blue-grey infrastructures such as offshore longlines and rafts. Integrating biobased aquaculture gears into these infrastructures could enhance their effectiveness as nature-based solutions (NbS). The findings from this study will be used to assess the efficacy of these infrastructures as NbS in TRANSEATION project and to guide the implementation of biobased gears in the aquaculture sector.

**Methodology and aims**

In the TRANSEATION project, two new biobased rope prototypes (T1 and T2) have been developed, enhancing the mechanical characteristics of the best-performing biobased B2 rope prototype in the previous BIOGEARS project. All three biobased prototypes (T1, T2, B2) are based on compounds of commercially available biopolymers and manufactured with industrial processes to be fit-for-purpose, with the required technical and functional properties to be a cost-effici9ent alternative to the conventional fossil-based mussel rope counterpart (GR). Throughout 2024 and early 2025, the setup of a longline and a raft as low trophic aquaculture demonstrators was carried out, which included maintenance and repair activities on the infrastructures. Additionally, several pieces of equipment were installed in the infrastructures, including current meters, pH meters, acoustic sensors, and chlorophyll sensors, aiming to continuously monitor environmental parameters that can impact mussel and seaweed cultivation. Before setting up the cultures, a monitoring plan for the environmental parameters was established, along with the experimental design for the aquaculture trials at sea.

Aiming to evaluate the efficacy of the low trophic aquaculture infrastructures as NbS, the following steps were also undertaken: 1) the development of a System Approach Framework (SAF) into an applicable ecosystem-based management (EBM) Framework that provides a systematic and stepwise guidance for the planning, development, implementation, monitoring and evaluation of hybrid NbS, 2) the establishment of a framework with the identification of indicators to evaluate the benefits and potential trade-offs of these NbS, particularly concerning marine biodiversity and ecosystem services protection and restoration. Finally, in May 2025 the setup of the culture of mussel seeded in biobased rope prototypes (B2, T1, T2) and fossil-based counterparts (GR) was conducted.

**Results**

The preliminary results on the aquaculture performance of the biobased ropes compared to fossil-based counterparts will be presented regarding the evolution of mussel growth and rope mechanical properties. Besides, the adjustment of the established frameworks to the infrastructures will be assessed.

# FROM WATER BIOREMEDIATION TO SEA URCHIN FEED: *Ulva ohnoi* ENHANCES SUSTAINABILITY IN RECIRCULATING AQUACULTURE SYSTEMS FOR SEA BREAM (*Sparus aurata)* AND SEA URCHIN (*Paracentrotus lividus)* PRODUCTION

J. Araújo*, A. C. Carvalho, A. C. Matias, M. C. Ribeiro, F. Soares, P. Pousão-Ferreira

IPMA- Portuguese Institute for the Ocean and Atmosphere
EPPO- Aquaculture Research Station
Olhão, Portugal
E-mail: joao.araujo@ipma.pt

**Introduction**

Recirculating Aquaculture Systems (RAS), particularly when combined with Integrated Multi-Trophic Aquaculture (IMTA), can improve sustainability by enhancing nutrient recycling and fish health (Cesare Marincola et al., 2025)). *Ulva ohnoi* contributes to these systems through bioremediation and nutritional value (Chatzoglou et al., 2020), and its bioactive compounds may help control parasitic infections like monogeneans (Doan et al., 2020). This study assesses a multitrophic RAS integrating *S. aurata* and *U. ohnoi*, focusing on algal productivity, use as feed for *Paracentrotus lividus*, and effects on fish health.

**Material and methods**

Two identical recirculating aquaculture systems (RAS) were used to integrate *U. ohnoi* cultivation with *S. aurata* rearing. In Phase I, macroalgal productivity and its use as exclusive feed for *P. lividus* were assessed. In Phase II, fish were reared in systems with (A) and without (B) macroalgae to evaluate effects on growth and monogenean infection. Each RAS included filtration units, a protein skimmer, two 3 m³ fish tanks, and nine 200 L algae tanks. Algal biomass, fish and urchin growth, and parasite load (assessed via gill scrapes and egg collection on artificial substrates) were monitored. Environmental parameters were recorded. Nutrient excretion was estimated via mass balance, and statistical analyses included GAMs and PCA, with inferential statistics (ANOVA, Dunn's test).

**Results**

In Phase I, *U. ohnoi* exhibited variable biomass gains with significantly higher growth in early autumn (24.4%) and reduced performance during winter (<10%). Biomass production showed no strong correlation with environmental variables (temperature, photoperiod, radiation). Estimated nutrients excretion by fish showed weak correlations with macroalgal productivity. Sea urchins displayed the highest growth during autumn, with declining SGR and gonad index over time, suggesting seasonal effects on feed conversion efficiency. In Phase II, *S. aurata* reared in systems with and without macroalgae showed similar growth performance and nutritional indices. However, monogenean parasite prevalence and egg deposition were consistently lower in the macroalgae-integrated system, particularly at intermediate temperatures (20–21 °C), indicating a potential mitigating effect of *Ulva* on ectoparasite dynamics. Despite a resurgence of infection in late spring, systems with *U. ohnoi* maintained lower parasite loads and egg counts than controls.

**Discussion**

This study demonstrated the viability of integrating *U. ohnoi* cultivation within a multitrophic RAS for *S. aurata*, with macroalgal biomass used to feed *P. lividus*. *U. ohnoi* showed stable productivity across autumn and winter, despite seasonal fluctuations in temperature and radiation. No strong correlation was found between biomass and environmental or nutrient variables, likely due to *Ulva*'s high ecological plasticity and the buffering effect of RAS conditions. Sea urchins fed exclusively with fresh *U. ohnoi* exhibited moderate growth and gonad development, within expected biological ranges, however its sustainability and low cost support its use in integrated systems, and its inclusion in formulated feeds has further demonstrated beneficial effects. For *S. aurata*, macroalgae inclusion had no major effect on growth performance, but ectoparasite prevalence and egg deposition were temporarily reduced in the macroalgae-integrated system. These findings suggest a potential role of *U. ohnoi* in parasite control, though further research is needed to confirm its consistency and mechanisms.

* joao.araujo@ipma.pt

**Introduction**

Fisheries and aquaculture are long-established activities in the Atlantic region, representing a key source of economic and social value. These sectors supply a wide range of products for the food, pharmaceutical, and biotechnology industries, yet they also generate large amounts of by-products that are frequently discarded or directed to low-value applications. Increasing awareness of circular economy principles offers an opportunity to transform these underutilized resources into innovative products with higher commercial and societal value. The AQUAFISH0.0 project promotes a sustainable, zero-waste approach by developing high-value products from fisheries and aquaculture by-products, as well as from low-value catches and invasive seaweed species. The consortium involves institutions from Portugal, Spain, France, and Ireland, combining expertise across multiple disciplines. Within this framework, the IPMA is responsible for designing, developing, and characterization of functional products, optimizing sea urchin aquaculture through integrated use of seaweed, and assessing nutritional risks and benefits to provide dietary recommendations. Additionally, IPMA will promote awareness and acceptance of sustainable marine products through education and outreach activities.

**Material and methods**

At the IPMA Aquaculture Station (EPPO), the use of aquaculture by-products in the form of seaweed was tested under two Integrated Multi-Trophic Aquaculture (IMTA) conditions: (A) earthen ponds and (B) a Recirculating Aquaculture System (RAS)-based bioremediation system

A. Earthen Pond trial: A 2250 m² pond was stocked with meagre (*Argyrosomus regius*), gilthead seabream (*Sparus aurata*), and white seabream (*Diplodus sargus*) at a density of 1.3 kg $m^{-3}$. Six floating cages were installed: each inoculated with 2 kg of *Ulva ohnoi* (n=3) or *Gracilaria gracilis* (n=3). Seaweed biomass was harvested every 15 days, and yields were used to feed sea urchins (*Paracentrotus lividus*). The trial lasted 40 days, during which urchin feeding and growth were monitored.

B. RAS trial**:** A recirculating aquaculture system for gilthead seabream (*S. aurata*) was set up, incorporating a bioremediation unit based on *U. ohnoi*. Over 180 days, the system was evaluated in terms of macroalgal biomass production, fish growth performance, and the application of *U. ohnoi* as feed for sea urchins.

C. Future trial with invasive macroalgae**:** The next step will assess the use of the invasive brown seaweed *Rugulopteryx okamurae* as feed for sea urchins (*P. lividus*). This species, with no commercial value and a major negative ecological impact in the Mediterranean and Atlantic, will be tested both as dried biomass and as an ingredient incorporated into formulated inert diets. Control groups will be fed with dried *U. ohnoi* and equivalent inert diets. The trial will evaluate feed acceptance, growth performance, and the sensory quality of gonads.

In parallel, the Aquaculture, Valorization and Bioprospecting Division (DivAV-IPMA) developed a functional food prototype using aquaculture and fisheries by-products as raw material: the red seaweed *G. gracilis*. Two trials were carried out: (1) development of innovative functional food (Sea Nachos"), and (2) evaluation of its nutritional value through physicochemical, biochemical, biological activity (antioxidant and anti-inflammatory properties), sensory, and bioaccessibility study (by using an *in vitro* digestion model that simulates human digestion), also considering culinary treatment.

*(Continued on next page)*

**Results**

In the first trial with seaweed cultivated in earthen ponds (A), *Ulva ohnoi* showed excellent adaptation to the culture conditions, with biomass increasing by approximately 126–150% over 15 days. In contrast, *G. gracilis* exhibited poor adaptation, being highly susceptible to contamination by marine fouling organisms, particularly bryozoans. Although an initial biomass increase of 63% was observed during the first 15 days, bryozoan overgrowth subsequently expanded exponentially, ultimately leading to the death of seaweed. In the second trial using the RAS-based bioremediation system (B), *U. ohnoi* again demonstrated strong adaptability to different culture environments, with consistent biomass production. Seasonal differences were observed, with lower yields during the winter months; however, no strong correlation was found between measured environmental variables and production levels. Regarding sea urchin (*P. lividus*) rearing, both trials confirmed high acceptance of macroalgae as feed, supporting adequate growth and normal gonad development in accordance with the species' natural reproductive cycle.

The development of an innovative functional food product demonstrated the potential of aquaculture and fisheries by-products as raw materials for functional applications. The functional food prototype, "Sea Nachos", enriched with the red seaweed *Gracilaria gracilis,* was successfully produced. The "Sea Nachos" were found to be rich in nutrients and bioactive compounds from *G. gracilis*: rich in iodine (10 µg/5 g nacho) and polyphenols (412 mg GAE/100 g dw), as well as, with high biological activity (mainly anti-inflammatory and antioxidant). The *in vitro* digestion assay showed high bioaccessibility of nutrients/bioactive compounds and biological activity, supporting its potential as a sustainable and healthy alternative in human diets. Furthermore, the sensory tests (performed by an international panel) indicated good consumer acceptance.

**Discussion**

The results obtained in earthen pond (A) and RAS (B) IMTA systems demonstrate that both approaches are effective for producing *U. ohnoi* biomass. In contrast, *G. gracilis* proved highly vulnerable to biofouling and therefore unsuitable under the tested conditions. The biomass of *U. ohnoi* showed excellent applicability as a staple feed for sea urchins, supporting a more cost-effective and sustainable aquaculture practice. This highlights the potential of valorizing aquaculture by-products, such as *U. ohnoi*, as a reliable raw material that contributes to circular economy strategies and zero-waste objectives. Regarding the developed functional food ("Sea Nachos"), it was shown that its consumption can make a difference in the promotion of a healthy diet and contribute to a more sustainable society. The "Sea Nachos" may contribute to adequate levels of iodine intake in diet (150 µg/day). Therefore, the incorporation of *G. gracilis* into the formulated nachos has made it possible to develop an affordable, sustainable and healthy product, allowing its consumption to add benefits beyond the usual nutritional ones.

**Introduction**

The objectives of the MARINET project (MARIculture NETwork, Interreg Italy-Croatia n. ITHR0200334) include the implementation of innovative technologies to promote diversified and sustainable aquaculture, thereby supporting public health and enhancing regional competitiveness. One of the main goals is to evaluate the applicability and effectiveness of the Integrated Multi-Trophic Aquaculture (IMTA) system when applied to the farming of European sea bass (*Dicentrarchus labrax*) and European flat oyster (*Ostrea edulis*), as developed under Work Package 2.

In recent decades, the inconsistent availability of food sources (particularly phytoplankton) for farmed bivalve molluscs has been one of the notable consequences of the climate crisis. In this context, the IMTA system may offer a promising solution. This study focuses specifically on flat oysters, aiming to support the revival of this historically important bivalve species in the Adriatic Sea. Currently, the Japanese cupped oyster (*Magallana gigas*) has largely replaced the flat oyster in commercial farming. However, *M. gigas* is considered an invasive alien species and is therefore not farmable in Croatia.

This study also aims to evaluate the feasibility of farming flat oysters using wild-caught seed collected in the Adriatic Sea with various trap types. The health status and production performance of the oysters are assessed, along with the effectiveness of different farming methods. Several types of lantern nets are placed at various depths to identify farming conditions that minimize stress for the animals. Finally, the oysters were subjected to bromatological analysis and condition index assessment to evaluate their commercial quality.

**Materials and methods**

Several production sites along the Italian and Croatian coasts were selected, each characterized by different trophic conditions. These were assessed using satellite data on phytoplankton concentrations, silicates, nitrates, and phosphates. The sites included Puglia, Emilia-Romagna, Friuli Venezia Giulia, and the Istrian coast.

At each site, approximately 2000 flat oysters were placed. In IMTA sites, lanterns were positioned both upstream and downstream of the current, with an additional control site located far from the farm. Different types of net and plastic lanterns, along with collectors with varying filtering and accumulation capacities, were used.

**Laboratory Analyses**

Pathogen analysis: cytological, histological and molecular tests.
Health and environmental stress biomarkers: IHC of HSP70, iNOS, Cox-2, Cyp1A and Caspase3.
Chemical analysis: Fatty acid profiles determined using a gas chromatograph (Agilent 7890B) coupled with a flame ionization detector (GC-FID), equipped with a DB-WAX column (Agilent)
Condition index: assessed according to the "Accord interprofessionel sur la denomination et la classification des huîtres creuses"
Phytoplankton analysis: UTERMÖHL technique, UNI EN 15204:2006.

*(Continued on next page)*

**Preliminary results**

Analyses are still in progress. In the first phase, several pathogens have been identified, including *Bonamia exitiosa* and *Perkinsus mediterraneus*, with some cases of co-infection. Epibionts such as the sponge *Cliona celata* and the parasitic bivalve *Rocellaria* spp. were also observed. Notably, some individuals showed signs of disseminated neoplasia.

Histological examination of the gonads confirmed active reproductive development even during winter months. In one IMTA farm, an increase in saturated fatty acid levels was observed, particularly in oysters located downstream from the fish farm. Overall oyster mortality has remained low and does not appear to be significantly influenced by the presence of pathogens.

**Discussion**

The detection of *Bonamia exitiosa, Cliona celata*, and *Rocellaria* spp. confirms that the study area is endemic for these pathogens. The presence of *Perkinsus mediterraneus* represents the first report of this parasite in the Adriatic Sea; prior cases had only been documented in the Balearic Islands (2004). The occurrence of disseminated neoplasia in some oysters needs further investigation.

High levels of saturated fatty acids observed downstream of the IMTA system support the hypothesis that flat oysters can utilize organic material derived from fish farm effluents. These preliminary findings suggest a potential benefit of IMTA systems in enhancing the nutritional value of oysters, which will need to be confirmed through stable isotope ratio analysis (C and N).

# PRELIMINARY EVIDENCE OF NURSERY POTENTIAL OF IMTA STRUCTURES FOR THE PURPLE SEA URCHIN *Paracentrotus lividus*

D. Arduini*[1,2], S. Fraissinet[1], A. Giangrande[1,2] and S. Rossi[1,2]

## Introduction

Integrated Multi-Trophic Aquaculture (IMTA) is a sustainable aquaculture practice that combines species from different trophic levels, typically fish, suspension-feeders, and macroalgae, within a single system to optimize resource use and reduce environmental impacts [1]. IMTA is increasingly promoted worldwide for its potential to curb excess (in)organic matter from high-trophic fish through water bioremediation and nutrient recycling by low-trophic extractive species while diversifying crop production [1, 2].

Artificial substrates used in marine aquaculture, such as ropes and nets, often become heavily colonized by macroalgae and sessile invertebrates such as ascidians, polychaetes, bryozoans and mollusks [3]. These fouling assemblages are considered a serious operational pest due to their damaging effects on farming structures and competition with cultured species, leading to increased maintenance costs for aquaculture sector [4]. However, they can also provide ecological benefits in mariculture environment, such as consuming excess organic matter and mitigating local environmental impacts [5-8].

In a novel multi-species IMTA-converted fish farm in southern Italy, natural fiber ropes were used to cultivate extractive filter feeders from fouling assemblages [9]. The resulting sessile complex fouling community covering the ropes, dominated by the polychaete *Sabella spallanzanii* (Gmelin, 1791), hosted rich associated fauna [7], including juveniles of the purple sea urchin *Paracentrotus lividus* (Lamarck, 1816).

In the Mediterranean, this species has undergone severe population declines due to overfishing and marine heatwaves, especially in the Apulia region (Southern Italy), where a complete fishing ban has been in place since 2023 [10]. However, passive restoration alone may be insufficient and habitat provisioning in anthropogenic environments, such as aquaculture structures, could offer a complementary recovery pathway.

This preliminary study aims to provide the first insights into the nursery potential of the fouling communities highlighting their ecological value and exploring the role of IMTA structures in supporting biodiversity and sea urchin recovery.

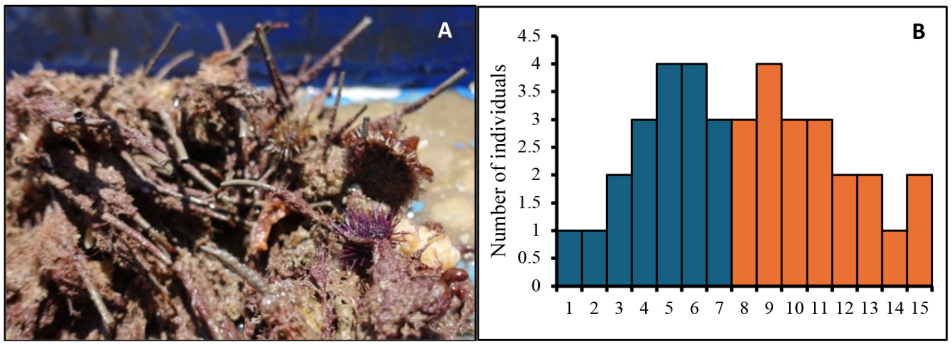

Figure 1. Two specimens of *P. lividus* (purple in the foreground and greenish in the background) found during sampling (A). Size-frequency distribution in two cohorts (blue and orange bars) of individuals of *P. lividus* collected in July 2024. Size classes (mm): 1 = 10-11; 2 = 11-12; 3 = 12-13; 4 = 13-14; 5 = 14-15; 6 = 15-16; 7 = 16-17; 8 = 17-18; 9 = 18-19; 10 = 19-20; 11 = 20-21; 12 = 21-22; 13 = 22-23; 14 = 23-24; 15 = > 24).

*(Continued on next page)*

**Materials and methods**

The study area is located in the Mar Grande of Taranto (40°25′56″ N; 17°14′19″ E, Ionian Sea), a semi-enclosed basin connected to the Gulf of Taranto. The investigation was performed in the aquaculture plant "Maricoltura del Mar Grande", hosting the innovative IMTA system. In October 2023, 196 natural fiber ropes (10 m in length) were deployed around fish cages to promote macrofouling growth as IMTA extractive component. In July 2024, six ropes were randomly selected to evaluate the occurrence of juvenile sea urchins. All individuals of *P. lividus* found in the fouling communities were counted and measured in test diameter (without spines) using a digital caliper (resolution 0.1 mm). Based on test diameter, sea urchins were divided into 15 size classes, at 1-mm intervals. Size-frequency distribution was examined to identify cohorts, and mean ± SD were calculated for each. Counts were scaled up to estimate potential abundance across the 196 ropes.

**Results**

A total of 38 individuals of *P.lividus* (Fig. 1A) and 1 of *Arbacia lixula* (Linnaeus, 1758) were recorded, with diameters ranging from 10.0 mm to 24.6 mm. Two size cohorts were identified (Fig. 2A): cohort 1 (n = 18, blue bars), mean diameter = 14.28 ± 1.74 mm; cohort 2 (n = 20, orange bars), mean diameter = 20.38 ± 2.20 mm. The density of the sea urchins was 6.3 ± 5.9 individuals per rope, resulting in a potential production of about 1250 specimens at IMTA farm scale.

**Discussion**

These preliminary observations indicate that fouling communities developing on IMTA ropes may act as nursery habitats for juveniles of the purple sea urchin *P. lividus*, which could be later utilized for repopulation purposes. The detection of two distinct size cohorts suggests multiple recruitment events, a pattern consistent with the extended reproductive period of *P. lividus* in the Ionian Sea [11] and with settlement dynamics observed in other Mediterranean habitats [12]. Based on reported early-stage growth rates of about 2-3 mm/month [13], the individuals of cohort 1 likely settled in early spring 2024, while the larger ones may have originated from recruitment in late autumn-winter 2023-2024.

The species' slow growth and late maturity - typically 3-5 years to reach reproductive size in the Mediterranean Sea [11, 14] - imply that natural population recovery in overfished areas is likely to be a prolonged process, particularly under the additional stress of warming events [10]. While hatchery-based restocking has been attempted [15], these efforts are often constrained by high mortality occurring in both larvae and early juveniles, as well as by the need for cost-effective grow-out systems. In this context, natural recruitment onto aquaculture structures offers a potentially sustainable and low-cost alternative. The fouling assemblages on IMTA ropes, composed of sessile invertebrates, not only mitigated organic matter loading from fish farms [8] but also provide structurally complex habitats resembling marine animal forest [16] that attract a diversity of associated fauna, including species of commercial interest [7]. Although sea urchin abundance on the ropes was highly variable, the IMTA farm has the potential to produce approximately 1,250 individuals of *P. lividus*, which could be reintroduced into natural environments to support population restoration. The scalability of this approach would depend on the total number of ropes deployed in the IMTA system.

Although based on a single sampling event, this study provides preliminary evidence that IMTA ropes can serve as effective nursery habitats for *P. lividus*, offering a cost-effective, nature-based approach that aligns aquaculture production with biodiversity conservation and restoration objectives [17-18]. In their juvenile stage, sea urchins and possibly other organisms find shelter from predators within the forest structured by sabellids and other sessile species, including macroalgae that may also serve as a food source. Long-term, seasonal monitoring will be essential to quantify recruitment patterns, assess in situ growth and survival, and evaluate the feasibility of incorporating IMTA structures into integrated restoration and conservation management strategies.

[2] Immunobiology for Aquaculture Group, Department of Cell Biology and Histology, Faculty of Biology, University of Murcia, 30100 Murcia, Spain

**Introduction**

Species diversification in aquaculture is essential to assure sustainability as well as reducing disease risks. One of the species under evaluation to be introduced in the Mediterranean aquaculture is shi drum (*Umbrina cirrosa*). Their adaptation to captivity, docile handling and their reproduction conditions are excellent characteristics to be considered a good candidate for species diversification (Abellán et al., 2013). However, up to date, very little is known about their susceptibility to pathogens or immunity (Chaves-Pozo et al., 2021). Parasite infections are a great threaten in aquaculture with negative economic impact. Outbreaks of the protozoan ciliate *Cryptocaryon irritans* cause mortalities up to 100% in Mediterranean fish species (Cervera et al., 2022). *C. irritans* complex life cycle difficults its rapid detection and treatment (Li et al., 2021). The objective of this work is to characterize the immune response of shi drum against a severe *C. irritans* infection.

**Material and methods**

In the facilities of Centro Oceanográfico de Murcia (COMU-IEO, CSIC) *C. irritans* outbreaks are quite frequent when temperatures are over 20 ºC. In the case of this study, sudden mortalities, and severe skin injuries appeared in a stock of shi drum. *C. irritans* infection was confirmed by the observation of the trophonts under the binocular loupe. During the 20 days that this infection episode lasted, mortality reached 100%. Samples of serum and head-kidney (HK) were taken in days 1, 2, 3, 4, 5 and 8 from the start of the mortalities (dpi). Homogenates of HK were prepared at a concentration of 1 g of tissue in 1 mL of PBS (pH 7.4). Total levels of proteins were measured by direct UV absorption. Humoral immune response at systemic level was evaluated by analyzing peroxidase, antiprotease and bactericidal activities in serum and HK homogenates following previously described protocols (Cervera et al., 2022).

**Results**

Peroxidase activity increased along the time in both HK and serum reaching the highest level at 8 dpi. Antiprotease activity was significantly increased in the HK at 1 dpi but in the serum did at 5 dpi, returning then to similar levels as the control. In both cases, bactericidal activity decreased along the time becoming undetectable from day 3 onwards in serum, while in HK a progressive decrease was observed from day 4 onwards.

**Discussion and conclusions**

Systemic humoral response of shi drum was modulated by *C. irritans* infection. The fact that only peroxidase activity increased along the infection point to an inefficient way to control the disease. In fact, the transitory increase of antiprotease activity, key to neutralize the parasite proteases (Siqueira-Neto et al., 2018), occured at the same time as the blockage of the bactericidal activity. These data point to certain immunosuppression triggered by the parasite to evade the immune response as described for other parasites (Holzer et al., 2021).

[2] Immunobiology for Aquaculture Group, Department of Cell Biology and Histology, Faculty of Biology, University of Murcia, 30100 Murcia, Spain

**Introduction**

Antimicrobial peptides (AMPs) are short aminoacidic peptides widespread in nature. AMPs can modulate the host immune response and directly kill pathogens such as viruses, bacteria, or parasites (Katzenback, 2015). AMPs are a very diverse group, which is divided into families. In this project, we focused on beta-defensins (Bdef), a family characterized by the presence of conserved cysteines and disulfide bonds (Das et al., 2022). The presence of Bdef in reproductive tracts has been reported, especially the males, in which Bdef plays its role in reproduction and immune-endocrine regulation (Jing et al., 2010). In teleost fish, several pathogens such as betanodavirus (NNV) can colonize the gonad causing latent infection, which can be transmitted to their progeny (Valero et al., 2018). In this case, NNV control in the gonad results key to overcome potential outbreaks in fish farms. Basing on the available literature, the objective of this work is to deepen in the molecular characterization of the two *bdef* transcripts in European sea bass (*Dicentrarchus labrax*), *bdef1* and *bdef2*, upon diverse conditions in testes.

**Material and methods**

Testes and ovaries from a broodstock of European sea bass were collected. Testes of healthy specimens of European sea bass were sampled monthly to study Bdefs gene expression during the male reproductive cycle (Valero et al., 2015a). Also, males were injected with culture medium alone or containing $10^6$ $TCID_{50}$ of RGNNV/fish. Testes were removed after 1-, 7- and 15-days post-infection (dpi) (Valero et al., 2015b). All samples were processed for gene expression analysis using qPCR.

**Results**

The expression levels of *bdef1* were similar in testis and ovary while *bdef2* expression was higher in testis. Besides, the transcriptional levels of *bdef2* were higher than *bdef1* in testis. During the male reproductive cycle, the highest expression of *bdef1* occurred during spermatogenesis stage while *bdef2* was more expressed in spawning stage. During NNV *in vivo* infection *bdef1* was up-regulated at 7 dpi while *bdef2* remained unaltered.

**Discussion and conclusions**

The transcription of *bdef* in European sea bass gonads has been reported for the first time. As for other species Bdef, *bdef2* seems to be preferentially expressed in the male reproductive tract (Jing et al., 2010), pointing to their role in sperm preservation. Considering this, we have focused on the expression of *bdef* in males. Along the male reproductive cycle, *bdef1* and *bdef2* resulted differently modulated suggesting different functionalities for each gene. The pattern of expression of *bdef1* in gonad upon NNV infection is similar to another AMPs (Valero et al., 2015). Our results point to *bdef1* as an antiviral molecule in the testes. Further studies are mandatory to clarify the differences in regulation of both transcripts.

# COMPARING EPIDEMICS AND CONTROL MEASURES FOR SALMONID DISEASES USING NETWORK MODELLING

Sophie Armitage*, Adam Kennerley, Sarah Alewijnse, Mark Thrush, Mickael Teixeira Alves

Centre for Environment Fisheries and Aquaculture
The Nothe, Barrack Road
Weymouth, DT4 8UB, United Kingdom
Email: sophie.armitage@cefas.gov.uk

**Introduction**

Infectious diseases pose a major threat to aquaculture sustainability. Once introduced, aquatic diseases can propagate rapidly through highly connected aquaculture sites and cause substantial production losses due to increased mortalities. Surveillance and control measures such as contact tracing, culling and fallowing are vital for preventing this spread and mitigating impacts on both the industry and the environment. However, the epidemiological and economic impact of these activities may differ depending on the characteristics of the controlled disease. By improving our understanding of specific disease dynamics within aquaculture networks, control strategies can be tailored to be the most effective and impactful, whilst minimising the economic burden to the industry and the competent authority.

England & Wales are free from infectious hematopoietic necrosis virus (IHNv) and viral haemorrhagic septicaemia virus (VHSv), two serious salmonid diseases listed by the World Organisation for Animal Health (WOAH) and nationally controlled under the Aquatic Animal Health (England & Wales) Regulations (2009). Using a network modelling framework, this study aims to compare the complex interplay of epidemics and control measures between the two diseases and contribute evidence to inform tailored disease preparedness.

**Materials and Methods**

The modelling framework, AquaNet-Mod, was adapted and applied to IHNv and VHSv outbreaks in salmonid aquaculture in England & Wales (Guilder et al. 2023). AquaNet-Mod simulates disease transmission within the network via river connections and live fish movements, integrating data collected by the competent authority through statutory monitoring.

Here, an extensive literature review and expert elicitation was conducted for parametrising specific disease characteristics in the model, such as life cycle stages and seasonal changes. Subsequently, a comparative analysis was conducted to compare the epidemic dynamics between the two diseases and evaluate the effectiveness of various control measures from an epidemiological and economic perspective. Finally, disease characteristics that drive differences in transmission dynamics and efficiency of control measures were identified using sensitivity analysis.

**Results**

This study found significant differences in disease dynamics throughout the England & Wales aquaculture network, with IHNv epidemics resulting in larger and more costly epidemics than VHSv. For instance, the average overall cost of a IHNv epidemic was 26% higher than an VHSv epidemic under the current control measures in England & Wales. Control measures were, however, shown to similarly prevent the spread and impact of both diseases, notably with a significant decrease in the size, duration and cost of the epidemics. Subsequently, the importance of specific disease control measures, particularly contact tracing, catchment controls and fallowing period were shown. Key disease characteristics, such as seasonality and virus decay rate in sediment, were identified as primary drivers of these differences in transmission and impact.

**Discussion**

This study facilitates key comparisons between the dynamics of two serious salmonid diseases, aiding informed decision-making with respect to tailored disease control management. The results of this study confirm the vital role disease control strategies play in preventing larger, more costly epidemics, regardless of the disease. Furthermore, it shows the value of mathematical modelling frameworks in better understanding complex interactions between epidemiological and economic impacts of epidemics and control measures, providing evidence to justify the application of effective balanced control strategies, informing resource allocation and enhancing disease preparedness.

*(Continued on next page)*

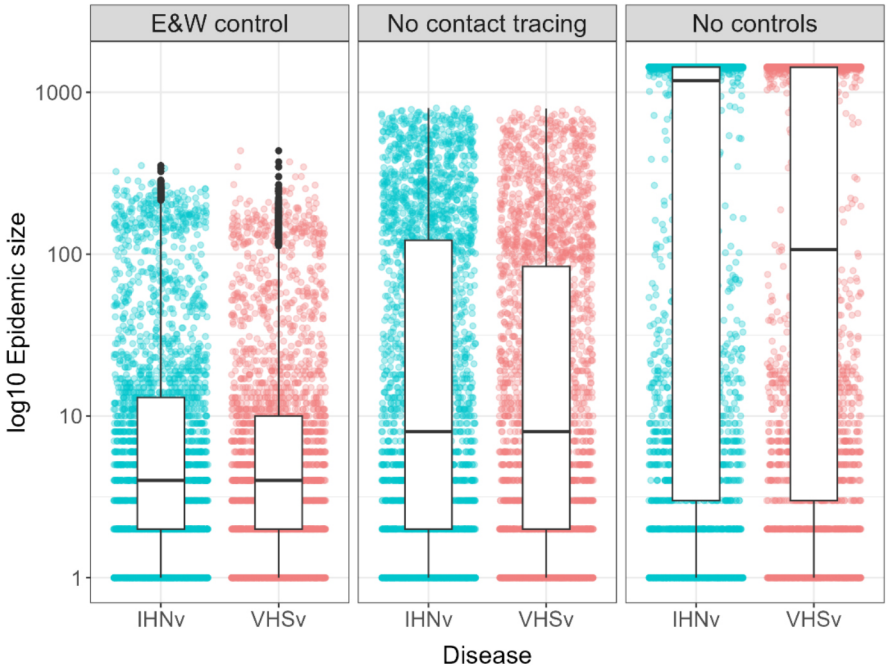

**Figure 1.** Box plot displaying the epidemic size defined as the number of sites infected throughout the duration of the epidemic for both IHNv (left bar, blue) and VHSv (right bar, pink) from simulations conducted in the England &Wales salmonid network under current control measures in (left), contact tracing removed (middle), and all controls removed (right). This data is derived from 3,000 simulations, each lasting 10 years or until the infection ceases for each scenario. The epidemic size is represented using a log-10 scale.

## Introduction

The aquaculture industry has seen rapid growth over the last decades. This growth, however, presents new challenges in terms of ensuring efficient, safe, and sustainable operations [1]. Fish farming often involve a significant amount of manual labor, which can be physically demanding and dangerous. Tasks such as net inspection, maintenance, and repairs expose workers to hazardous underwater conditions, including rough seas, low visibility, and the presence of potentially harmful marine life. Addressing some of these problems, the interest in robotic systems for aquaculture has also grown significantly in recent years [1]. However, in order to have robust systems operating in dynamic environments we need to increase the level of autonomy of underwater vehicles operating in fish farms. This paper presents a general framework that integrates visual and acoustic sensor data to enhance localization and mapping in complex, highly dynamic underwater environments, with a particular focus on fish farming.

This work was financed by the Research Council of Norway through the project: CHANGE [2] and ResiFarm [3].

## Materials and methods

Fig. 1 provides a brief overview of the proposed underwater localization and mapping framework, which allows UUVs to operate in dynamic underwater environments [4]. The proposed framework investigates vision-based methods to: 1) obtain the relative 3D pose of an UUV from a flexible and deformable structure to facilitate control strategies for autonomous net inspection operations in fish farms, 2) construct the depth map from mono-vision data that can be crucial for both collision-free autonomous operations with UUVs in dynamic environments and for obtaining the real-time map of the inspected area to identify irregularities such as holes, or biofouling in net pens, 3) estimate the global pose of an UUV within the net pen utilizing the available sensor measurements and relative poses of the robot, and 4) create a detailed 3D map of the net-pen environment utilizing data obtained from an industrial scale fish farms (Fig. 1).

## Results

This section presents evaluations across four key areas: relative poses, depth image predictions, global pose estimates, and mapping [4]. Field trials have been conducted in SINTEF ACE facilities to obtain the datasets for validation of the method. Fig. 2 shows the net relative distances estimated where the distance measurements from the DVL and the forward-facing ping echo sounder are compared with distance estimates obtained from the modified FFT-based method (Method 1), the TRU-depth (Method 2) and the Radar Meets Vision (Method 3), while Fig. 3 and Fig. 4 show the depth predictions and obtained map.

## Conclusion and future work

This paper presents a vision-based framework for underwater localization and mapping, using a large dataset from industrial fish farms. The approach employs FFT-based priors to support TRU-Depth and Radar Meets Vision methods, enabling depth prediction from monocular images for 3D mapping. It also proposes techniques for estimating both net-relative and global poses of UUVs. Results show that combining depth prediction, wavemap methods, and pose estimation produces accurate volumetric maps, demonstrating real-world potential in underwater environments. Future work could integrate priors based on fish or other structures to enhance 3D scene reconstruction.

## Introduction

Two variables are crucial in the intensive production of marine bivalves: the biochemical composition (BC) of food supplied together with the occurrence of large inter-individual differences in growth performance of endogenous origin. Quantitative knowledge of the effects of these variables and their interactions is of great interest for hatchery management, providing both useful information for the formulation of optimal diets and criteria for the eventual selection of high performance lines. Regarding BC, the effects of variable proportions of lipid to carbohydrate in the diet has been extensively studied (mainly in clams) in the search for non-phytoplanktonic supplements that can reduce phytoplankton production costs in bivalve rearing (Laing, 1987; Albentosa et al., 2002; Mamat & Alfaro, 2014). The present study investigates the effects of mixed diets with varying lipid/carbohydrate ratios on a) the growth and physiological performance and b) the elemental (C, N) composition and stoichiometric balances in fast- and slow-growing phenotypes of juvenile carpet shell clams (*Ruditapes decussatus*), focusing on homeostatic nutrient regulation, stoichiometric adjustments, and biochemical composition of body tissues.

## Materials and methods

Juvenile clams from the same cohort were segregated into fast (F) and slow (S) growing groups. They were subjected to a controlled diet comprising varying lipid/carbohydrate ratios, with constant C:N ratios. The composition of the diet differed according to the proportions of the microalga *Rhodomonas lens* and the yeast *Saccharomyces cerevisiae* (D1: 80% - 20%; D2: 50% - 50%; and D3: 20% 80%, respectively). Physiological parameters such as clearance rate, absorption efficiency, ammonium excretion rate and metabolic rate were measured to determine the scope for growth (SFG). These parameters were then utilised to calculate elemental balances (C and N) by means of analysis of their C and N contents in food and faeces. Finally, the clams were freeze-dried in order to ascertain their biochemical composition by means of conventional colorimetric procedures (see Arranz et al., 2021).

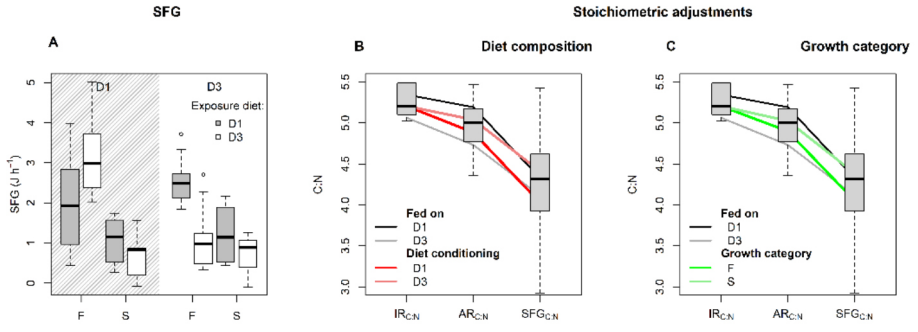

Figure 1. *A)* SFG (standardized values) of F and S clams exposed to diets D1 (gray boxes) and D3 (white boxes), and conditioned to diets D1 (shaded areas) and D3 (white areas). *B)* and *C)* Stoichiometric adjustments represented by C:N ratios for IR, AR and SFG. The lines represent the trajectory of each group combination, where the effects of feeding (exposure diet) on either D1 (black) or D3 (grey) are combined with the effects of conditioning (*1B*, red lines) and growth category (*1C*, green lines).

*(Continued on next page)*

**Results**

Dietary effects: Lipid-rich diets significantly enhanced SFG (Figure 1A) and elemental balances in juvenile clams. Clams conditioned to lipid-rich diets exhibited higher energy balances compared to those fed carbohydrate-rich diets. The biochemical composition of body tissues reflected the dietary content, indicating limited ability for homeostatic compensation. However, F clams showed a higher degree of tissues homeostasis.

Phenotypic differences: Fast-growing clams (F) showed greater phenotypic plasticity compared to slow-growing clams (S). This plasticity allowed fast-growing clams to better manage nutritional limitations imposed by different diets. For instance, fast-growing clams increased their clearance rates by 25% when fed carbohydrate-rich diets, compensating for the lower energy content (Figure 1A). In contrast, slow-growing clams exhibited only a 10% increase in clearance rates under the same conditions, indicating a lower capacity for compensatory feeding.

Stoichiometric Adjustments: Stoichiometric adjustments (Figure 1B and 1C) were primarily post-absorptive, with significant differences observed between diets and growth phenotypes. Fast-growing clams maintained a more stable C:N ratio (around 4.0) in their tissues across different diets, suggesting efficient nutrient regulation, while slow-growing clams exhibited a wider range of C:N ratios (3.8 to 4.5).

**Discussion and conclusion**

Conditioning to a high lipid content diet enhanced physiological compensations, allowing juvenile clams to face acute nutritional deficits. In contrast, the low lipid content diet reduced digestibility and impaired lipid balances. Lipid-rich diets significantly improved growth performance, especially in fast-growing phenotypes, highlighting the endogenous origin of growth differences. Fast growers achieved better physiological status under high-quality diets, enabling effective compensation for acute changes. Slow growers showed higher nitrogen release, indicating less efficient protein turnover. Stoichiometric regulation involved changes in absorption patterns and postabsorptive regulation.

The enhanced growth rates and stoichiometric balances observed in clams fed lipid-rich diets highlight the importance of dietary lipid content for optimizing growth and physiological efficiency in bivalve aquaculture. Given the greater phenotypic plasticity and together with their higher degree of tissues homeostasis, the selection of fast-growing lines allows them to be more resilient to nutritional variations. However, replacing more than 50% of microalgal diets with inert diets can compromise growth and disrupt lipid and protein balances.

San Diego, CA, 92121, United States

aartiles@aquatechcenter.com

Achieving sustained genetic progress in aquaculture breeding depends on selecting genotyping tools with the optimal number of markers for a given breeding strategy. This presentation explores key factors influencing marker density requirements, including the number of traits, genome size, linkage disequilibrium (LD) breakdown, recombination rate, genotype-by-environment interactions (GxE), and the need for precise selection over multiple generations.

Multi-trait breeding programs require higher marker densities to capture genetic variation across traits such as growth, disease resistance, quality, and reproduction. Genome size also impacts marker density needs, influencing genome-wide coverage. LD breakdown and recombination rates affect marker effectiveness, requiring strategic placement to ensure critical trait regions are adequately covered. Balancing marker density with LD decay and recombination events is essential for long-term breeding program success.

This presentation highlights the importance of an adaptive approach to marker density planning, ensuring genotyping tools align with breeding program goals. By optimizing marker selection, aquaculture breeding programs can enhance genetic improvement efficiency, maximize selection accuracy, and sustain progress over generations.

# FROM WASTE TO FEED: TURNING FOREST BY-PRODUCTS INTO SUSTAINABLE INGREDIENTS FOR FISH FEED

Mojtaba Asadollahi, Shiromini Gamage, Firoz Shah and Erik Hedenström

Department of Natural Sciences, Design and Sustainable Development
Mid Sweden University
Sundsvall, Sweden
Email: mojtaba.asadollahi@miun.se

**Introduction:**
Aquaculture's rapid growth is driving demand for sustainable protein and fat sources, yet reliance on wild-caught fish and crops contributes to overfishing, land-use pressure, and environmental impacts. Lignocellulosic sidestreams, abundant by-products from forestry, agriculture, and bio-based industries, offer a promising sustainable alternative. In the Nordic region, the forest-based industry produces large volumes of lignocellulosic sidestreams such as lignocellulosic hydrolysates. This study evaluates selected sidestreams from mills in Nordic countries as fermentation feedstocks for microorganisms like bacteria, fungi and yeast, assessing their potential to produce lipids and proteins for sustainable aquaculture feed.

**Main results**
Lignocellulosic sidestreams from pulp and paper industries in Sweden and Norway including lignocellulosic hydrolysates from hardwood and softwood, were collected, homogenized, freeze-dried, and stored before use. Microorganisms like oleaginous yeast strains and fungi were cultivated in bioreactors containing 10 g $L^{-1}$ of each material, with fermentation conducted for six days under controlled and optimized conditions. Comprehensive analyses were performed before and after fermentation, including composition (cellulose, hemicellulose, lignin), CHN content, sugars, phenolic compounds, inhibitors, metals, lipid yields, and fatty acid profiles. Lipids were extracted using the Folch method, converted to FAMEs, and analyzed by GC, while sugars and inhibitors were quantified via HPAEC-PAD and HPLC, phenolics by LC–MS/MS.

**Results:**
This study demonstrates that side-streams from the pulp and paper industry can serve as fermentation feedstocks for microorganisms, enabling the production of high-value food and feed ingredients. Certain yeast strains were able to consume available sugars and showed the ability to metabolize phenolic compounds, suggesting that lignin-derived carbon could be converted into lipids and proteins through optimized bioprocessing. We obtained promising results in the production of omega-3, protein, and astaxanthin.

Frank.Asche@ufl.edu

The importance of industry clusters may vary over time. The benefits of being located in an industry cluster is normally largest in innovation intensive periods which often occurs in the initial phase as the inception of an industry. This can be important for industry location and regional policies, as companies located outside of an industry cluster is less likely to succeed when agglomeration externalities are important, while there may be no disadvantages associated with staying outside of the cluster for a more mature industry.

In this paper we investigate the presence of agglomeration externalities for the Norwegian salmon industry using a translog cost function. This is an industry where there is extensive evidence of industry clusters, but with highly dated data. There is increasing evidence that the industry is maturing and productivity growth is slowing down, and larger companies with internal knowledge networks is becoming increasingly important.

We find that there is a structural break in the estimated parameters between 2015 and 2016. As in earlier studies, we find evidence of agglomeration externalities in the first part of our data set. However, these disappears after 2015, changing the considerations that should be made when locating farms as well as the costs associated with awarding licenses based on regional policy considerations.

# DEVELOPMENT OF A CATIONIC LIPID-BASED NANOVACCINE INCORPORATING RECOMBINANT ISKNV MAJOR CAPSID PROTEIN FOR ASIAN SEABASS

Wanchai Assavalapsakul*, Lapasrada Wanish, Nabhasbhichayabha Daewang, Timothy J. Mahony, Jakarwan Yostawonkul, Puttarat Baoprasertkul, Nopadon Pirarat, Sirikorn Kitiyodome, Komkiew Pinpimai, Kitipong Angsujinda

## Introduction

Infectious spleen and kidney necrosis virus (ISKNV) poses a significant threat to Asian seabass (*Lates calcarifer*) aquaculture in Thailand, causing high mortality rates and economic losses. Traditional vaccination methods, such as intramuscular injections, are often impractical for large-scale operations due to the stress they impose on fish and logistical challenges. Consequently, alternative strategies like nanotechnology-based immersion vaccines are being explored to enhance vaccine efficacy and feasibility in aquaculture settings.

## Materials and Methods

ISKNV infection in diseased Asian seabass was confirmed via PCR assays. The major capsid protein (MCP) gene was amplified, cloned, and expressed in *E. coli* to produce recombinant MCP (rMCP), which was purified and structurally validated using SDS-PAGE, immunoblotting, and transmission electron microscopy (TEM). Cationic lipid nanoparticles were synthesized to encapsulate the rMCP at various ratios, and their physicochemical properties - including particle size, zeta potential, and polydispersity index (PDI) - were characterized to determine the optimal formulation. Immersion vaccination trials were conducted on juvenile Asian seabass, and immunological responses were assessed by measuring IgM levels and the expression of immune-related genes using quantitative real-time PCR (RT-qPCR).

## Results

The 1:2 rMCP-to-nanoparticle ratio showed optimal traits: <200 nm size (Fig. 1), positive zeta potential, and lowest PDI.

## Discussion

While injection vaccination remains prevalent, it is labor-intensive and unsuitable for small fish (Priya & Kappalli, 2022). Oral vaccines face challenges like antigen degradation in the gastrointestinal tract (Jin et al., 2021). Immersion vaccination emerges as a practical alternative, effectively stimulating systemic and mucosal immunity with less labor (Bøgwald & Dalmo, 2019). This study developed a CTAB-based nanoparticle immersion vaccine using recombinant ISKNV MCP, enhancing immune responses in juvenile Asian seabass. A 10 mg/L concentration was selected based on prior studies balancing efficacy and cost (Zhao et al., 2019). Challenges included the absence of specific anti-MCP IgM antibodies, limiting quantitative ELISA assessments, and difficulties in amplifying T cell-related genes. Future research should focus on the ISKNV challenge following treatment and explore broader applications across various fish species.

## Conclusion

The recombinant ISKNV MCP nanovaccine, administered via immersion, holds promise for ISKNV prevention in aquaculture.

*(Continued on next page)*

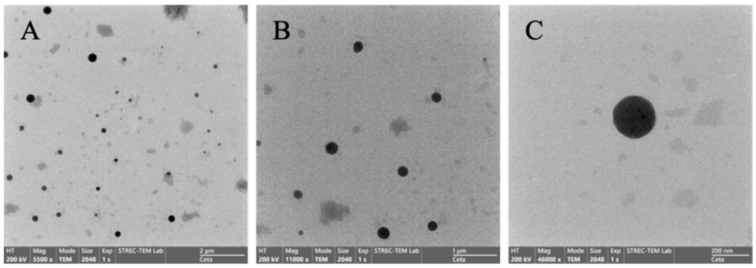

**Fig. 1** The rMCP of the ISKNV, combined with CTAB nanoparticles, was stained with 1% PTA and visualized using a TEM at 5,500 × (A), 11,000 × (B), and 46,000 × (C).

Fish treated with the rMCP nanovaccine showed significantly higher IgM levels (Fig. 2) and upregulated immune-related gene expression was observed at 14 and 24 days post-treatment.

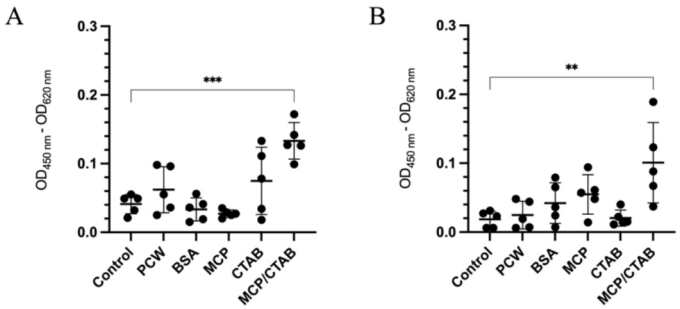

**Fig. 2** The level seabass at 14 days (A) and 24 days (B) post-treatment. Data are presented as mean ± standard deviation, with statistical significance indicated by ** ($p < 0.01$) and *** ($p < 0.005$).

# EVALUATION OF CHITOSAN BASED SOLUTIONS FOR FISH FILLETS PRESERVATION

E. Athanasopoulou*, T. Tsironi

Laboratory of Food Process Engineering
Department of Food Science and Human Nutrition
Agricultural University of Athens, Greece
efiatha@aua.gr

## Introduction

Due to the extended use of plastic and the associated environmental challenges, the European Union has introduced legislation to limit plastic production and waste accumulation. The European Parliament and Council (2024) support the use of eco-friendly packaging materials. By 2030, all plastic used in packaging must be fully recyclable. The use of biobased plastics from renewable resources aligns with these goals. Chitosan forms biodegradable, bioactive and biocompatible coatings. Its antimicrobial activity is attributed to cell membrane disruption, interactions with microbial gene expression, nutrient chelation, and the generation of reactive oxygen species (Khubiev et al. 2023). Global aquaculture reached 130.9 million tons in 2022 (FAO, 2023), but fish and seafood products are highly perishable due to their nutrient value, high moisture content, near-neutral pH, and high levels of unsaturated lipids and non-protein nitrogenous compounds (Kontominas et al. 2021). As a result, the selection of appropriate and environmentally friendly packaging materials is crucial to maintaining the quality of fish (Tsironi and Taoukis 2018). In the present study, active chitosan-based coating solutions were applied to fresh gilthead seabream fillets (*Sparus aurata*) to assess their potential for extending shelf life.

## Materials and methods

Chitosan-based solutions was produced by dissolving 1% w/v chitosan in 0.5% v/v acetic acid aqueous solution at 35°C. A 0.2% v/v organic citrus extract (coded as flavomix) was added as an active compound. The solutions were applied as coating materials on fresh gilthead seabream (*Sparus aurata*) fillets by immersing the fillets in the solution for 15 min. The samples were then dried at 2°C for at least 2 h. After drying, the samples were placed at sterilized Petri dishes and stored isothermally at 2°C. Three groups of samples were produced: uncoated samples (control), samples coated with 1% w/v chitosan (coating 1) and samples coated with 1% w/v chitosan enhanced with 0.2% w/v flavomix (coating 2). The three groups were subjected to shelf life evaluation by determining microbial growth, specifically Total Viable Count (TVC) and *Pseudomonas* spp. During the storage period, the optical appearance of the samples were evaluated using the CIELab system.

## Results and Discussion

Figure 1 presents the growth curves of TVC and *Pseudomonas* spp. fitted to the Baranyi Growth Model. The curves did not exhibit a lag phase. The initial load for TVC was 4.37, with no statistically significant differences between the three tested groups. Similar values have been reported by Koutsoumanis et al. (2002) and Spanou et al. (2024) as the initial microbial load of Mediterranean species. Control samples exhibited the highest growth rates for TVC and *Pseudomonas* spp. ($1.01\pm0.16$ $d^{-1}$ and $1.01\pm0.13$ $d^{-1}$, respectively). The growth rate of samples treated with coating 1 was $0.81\pm0.04$ $d^{-1}$ for TVC and $0.86\pm0.01$ $d^{-1}$ for *Pseudomonas* spp. Samples with coating 2 had a growth rate $0.44\pm0.02$ $d^{-1}$ for TVC and $0.60\pm0.02$ $d^{-1}$ for *Pseudomonas* spp. The maximum load of TVC ranged between 9.85-9.97 logCFU/g and 8.99-10.81 logCFU/g for *Pseudomonas* spp. According to Alexi et al. (2022) the limit of fish acceptability can be considered as 7 logCFU/g for TVC. Based on this limit, the shelf life of control samples was 2 days. The shelf life of samples treated with coating 1 was 4 days and the shelf life of samples treated with coating 2 was 6 days.

The results from the optical appearance assay were in agreement with the microbial tests. The lightness (L*) values of the control samples were statistically significantly lower than those of the samples treated with chitosan solutions during storage. Additionally, the control samples exhibited higher b* values at the end of the storage period, indicating that untreated samples shifted toward a yellow color more rapidly than those treated with chitosan-based coatings.

*(Continued on next page)*

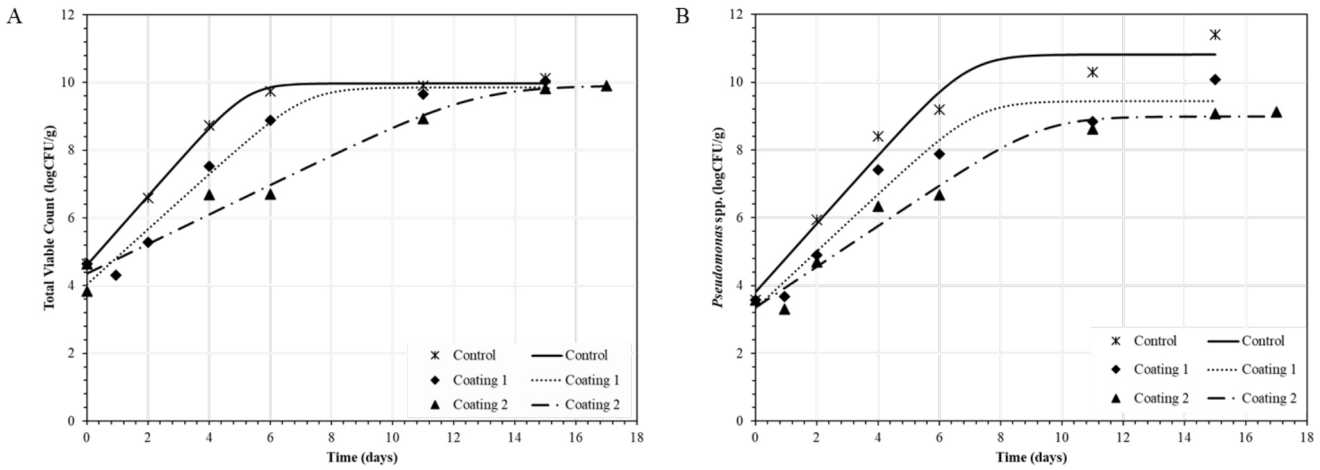

Figure 1 Microbial growth of (A) TVC; and (B) *Pseudomonas* spp. in gilthead seabream fillets stored isothermally at 2°C.

**Conclusion**

Chitosan based coatings are an effective packaging technique for extending shelf life and maintaining the quality of fresh fish fillets. Citrus extract can be successfully incorporated as an active compound in chitosan-based solutions, supporting sustainable food preservation practices.

# EFFECTS OF NUTRIENT AND ELECTRICAL CONDUCTIVITY STRESS ON EVAPOTRANSPIRATION AND STOMATAL CONDUCTANCE IN LETTUCE (*Lactuca Sativa*) GROWN IN AQUAPONIC SYSTEMS

Faiqa Atique [1 *], Oliver Körner [1]

Leibniz-Institute of Vegetable and Ornamental Crops
Grossbeeren, Germany
atique@igzev.de

## Introduction

Optimizing aquaponic production requires understanding how plants balance water loss and biomass accumulation under suboptimal nutrient and EC conditions. This study examines the physiological responses of lettuce to varying nutrient and EC levels in aquaponic systems to develop nutrient management strategies that enhance productivity and resource efficiency.

## Abstract

Understanding how plants regulate water loss and biomass under suboptimal nutrient and electrical conductivity (EC) conditions is key to optimizing aquaponic systems on the side of hydroponics plant production. This study examined physiological responses of lettuce (*Lactuca sativa* L. cv. Alyssa) grown in a nutrient film technique (NFT) system under six treatments varying nutrient concentrations (27%, 49%, and 76% of Sonneveld hydroponic solution) with or without EC control (~2.2 mS $cm^{-1}$). Treatments AP27 and AP49 (i.e., 27% or 49%, respectively) combined nutrient and fluctuating EC stress. Nutrients were supplemented at weeks 1 and 3, creating alternating phases of sufficiency and transient stress in weeks 2 and 4. Weekly evapotranspiration rate (E, mol $m^{-2}$ $s^{-1}$) and stomatal conductance to water vapour ($g_{sw}$, mol $m^{-2}$ $s^{-1}$) were measured with an IRGA gas analyser (Licor, LI-COR 6800). Linear mixed-effects models showed significant effects of treatment, week, and their interaction on E and $g_{sw}$. AP49 had higher E and $g_{sw}$ in week 1, reflecting higher stomatal activity under moderate nutrients without EC control, but these declined in weeks 2 and 4, aligning with nutrient stress periods. AP49fixed ("fixed" variant for controlled EC) showed consistently lower E and $g_{sw}$, indicating reduced physiological flexibility under fixed EC. Despite these shifts, AP49 achieved high biomass by week four, suggesting efficient resource use and partial decoupling of growth from water-use traits. The findings highlight that moderate, fluctuating nutrient regimes in aquaponics can boost productivity while conserving inputs and sustaining physiological resilience.

## Materials and methods

Lettuce (*Lactuca sativa* L., cv. Alyssa) was cultivated for 28 days in nutrient film technique (NFT) under six nutrient treatment regimes using hydroponic solution or decoupled aquaponic water (HP or DAPS). Each treatment had six independent replicates (gutters) with eight plants each. Plants 2 to 6 were sampled, with plants 1 and 8 as border plants. Evapotranspiration rate (E, mol $m^{-2}$ $s^{-1}$) and stomatal conductance for water vapour ($g_{sw}$, mol $m^{-2}$ $s^{-1}$) were measured weekly on the same plants in three replicates. To preserve plant identity for repeated measurements, destructive biomass sampling was performed weekly on the other three replicates. Nutrient concentrations were based on 76% Sonneveld solution (Sonneveld et al., 1999) for HP76fixed (control) and AP76fixed, and reduced to 49% and 27% in AP49fixed, AP27fixed, AP49, and AP27. Electrical conductivity (EC) was maintained between 2.2–2.3 mS $cm^{-1}$ in fixed treatments; EC fluctuated in AP49 and AP27. pH was maintained at 5.8 in all treatments.

## Statistical analysis

Fresh and dry weights were checked for normality and variance homogeneity, then compared across treatments weekly using one-way ANOVA with Tukey's post hoc tests based on three independent replicates per treatment for destructive sampling. Evapotranspiration (E) and stomatal conductance (gsw) were analysed using linear mixed-effects models with treatment, week, and their interaction as fixed effects, and plant ID as a random effect to account for repeated measures on three independent replicates used for non-destructive sampling. Degrees of freedom were approximated by the Satterthwaite method, and pairwise comparisons used Tukey adjustment. Analyses were performed in R version 4.4.1 (2024) using lme4, lmerTest, emmeans, and ggplot2. Significance was set at $\alpha < 0.05$.

*(Continued on next page)*

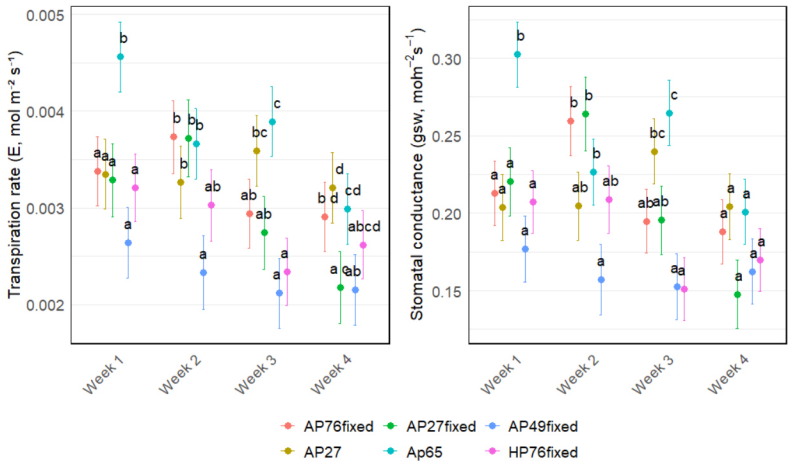

Figure 1: Weekly evapotranspiration rate (E, mol $H_2O$ $m^{-2}$ $s^{-1}$) and stomatal conductance ($g_{sw}$, mol $H_2O$ $m^{-2}$ $s^{-1}$) in lettuce across treatments. Values are estimated marginal means from linear mixed-effects models. Error bars show standard error. Letters indicate Tukey-adjusted significance groups ($\alpha = 0.05$), with comparisons made within each week.

**Results**

Significant effects of treatment and time were observed on evapotranspiration rate and stomatal conductance, with notable treatment × week interactions. The AP49 treatment exhibited higher E and $g_{sw}$ at week 1 compared to other treatments, indicating increased physiological activity under moderate nutrient levels without EC control. However, these values declined during weeks 2 and 4, coinciding with periods between nutrient applications and suggesting transient nutrient stress. In contrast, the AP49fixed treatment showed consistently lower E and $g_{sw}$, reflecting reduced physiological flexibility under fixed EC conditions (Figure 1). Despite these fluctuations, AP49 maintained high biomass accumulation by week 4, with significantly higher fresh weight (358.97 g ± SE 22.57) than AP76fixed ($p = 0.0188$), AP27fixed ($p = 0.0007$), and AP27 ($p = 0.0025$), indicating efficient resource use and partial decoupling of water-use traits from growth.

**Conclusions**

Moderate, fluctuating nutrient strategies combined with variable EC conditions can enhance stomatal regulation, water-use traits, and final biomass accumulation in aquaponic lettuce. The ability of plants to adjust transpiration and stomatal conductance under transient nutrient stress suggests potential for optimizing resource use without reducing growth. These findings support the use of dynamic nutrient management in aquaponic systems to balance productivity and sustainability.

# USE of *Musa acuminata* AS AN ANTI-STRESSOR AND WATER FOULING REDUCTION IN CULTURED *Clarias gariepinus Burchell, 1822*

Folalu Adekunle Awe *, Ayomide Bakare

Department of Fisheries
Faculty of Science
Lagos State University
Ojo, Lagos, Nigeria

E-mail:folaluawe08@gmail.com

Introduction
Water fouling reduction is needed in fish farming to reduce the number of times water is being changed. This study assessed the use of *Musa acuminata* as water fouling reduction and anti-stressor in cultured *Clarias gariepinus*.

Materials and Methods
Two hundred (200) fingerlings of *Clarias gariepinus* were purchased from LASU hatchery and stocked in a 500 litres tank for 3 weeks (21days) in order to induce stress on the fishes by overstocking, water was not changed and feeding was not regular and fed once per day.

After 3 weeks, the fishes were separated into two different tanks of 500 litre capacity each. Each tank (labeled 1-2) was stocked with 100 fishes each. For Tank 1- the control, no banana leaves were added while Banana leaves were inserted into tank 2 for a duration of two (2) weeks, The behavioural responses were recorded daily. Physical and chemical parameters of the water were recorded in the control and experimental tank containing banana leaves and later analyzed. The leaf extracts and the blanks were analyzed at the World Bank Step B Laboratory of the Federal Institute of Industrial Research, Oshodi, (FIIRO), Lagos State using the Atomic Absorption Spectrophotometer (SCHIMAZU-AA-7000).

**Table 1: Nutritional value of banana leaves**

| Parameters | Banana leaves | | |
|---|---|---|---|
| | $R_1$ | $R_2$ | Average |
| Carbohydrate | 85.15 | 85.10 | 85.13 |
| Protein | 3.67 | 2.68 | 3.18 |
| Fibre | 3.29 | 2.79 | 3.04 |
| Ash content | 1.18 | 1.26 | 1.22 |
| Moisture content | 7.01 | 7.00 | 7.01 |
| Fat content | 0.67 | 0.57 | 0.62 |

Results

Average values for control and experimental tanks were Dissolved oxygen (5.70) mg/L, Carbon IV oxide (2.30) mg/L, Ammonia (0.50) mg/L, Temperature (27.72$^{o}$C) and pH (6.65). Dissolved oxygen (3.75) mg/L, Carbon-dioxide (3.66) mg/L, Ammonia (1.20) mg/L, Temperature (26.38$^{o}$C), pH (7.98) respectively. Mineral content of the tank with banana leaf had Ca(994.86)mg/L, Mg(515.46)mg/L, K(1558.22)mg/L, Na (21.40)mg/L, Fe(1418.05)mg/L, Zn(202.07)mg/L, Pb(0.007)mg/L, Cu(22.03)mg/L, Mn(188.09)mg/L and Ni(0.0075)mg/L. The average nutritional value of the banana leaf in the tank contained carbohydrate (85.13%), protein (3.18%), Fibre (3.04%), Ash content (1.22%), Moisture content (7.01%) and Fat content (0.62%). The values in the tank containing the banana leaves were found to be higher but within the WHO permissible limits. The high values indicate a high mineral, chemical and nutritional content than the control tank. The GC-MS revealed the presence of hexadecanoic acid, Tocopherol (vitamin E), phytol and phthalates compounds and other twenty (20) chemical compounds obtained in *musa acuminata*. These chemical composition influences fouling reduction, and reduction of stress- related diseases in *Clarias gariepinus*.

Conclusion

Phytochemicals present in banana leaf infuses into the water and induces water fouling reduction for 30 days in stressed *Clarias gariepinus* fish in culturing system.

# LAYING THE MUSSEL PUZZLE: LIFE CYCLE ENVIRONMENTAL IMPACTS OF MUSSEL FARMING PRACTICES ACROSS THE NORTHEAST ATLANTIC

A. Axelsson*[1], Y. Wocken[1], P. Tyedmers[2], F. Ziegler[1]

[1]RISE Research Institutes of Sweden, Göteborg, Sweden
[2]Dalhousie University, Halifax, Nova Scotia, Canada
E-mail: anna.f.axelsson@ri.se

## Introduction

Farmed mussels have a special position among low-climate foods, much connected to their independence of manufactured feeds. This extensive and flexible production system of comparatively sustainable and nutritious food does not require specialised high-tech equipment and is therefore of special interest for a resilient food supply. The Mussel Puzzle is a three-year (2024-2026) research project, quantifying life cycle environmental impacts of farmed blue mussels in locations across the North Atlantic. One goal of the Mussel Puzzle is collecting and analysing systematic life cycle data for different forms of mussel farming. Additional goals are identifying improvement options in each system and evaluating what a large-scale expansion of production would mean in each location. Here we present first results for the life cycle environmental impacts of mussel farming using different techniques in three countries.

## Methods

We used Life Cycle Assessment (LCA) methodology to collect and analyse data on resource use and three categories of environmental impacts of mussel farming: greenhouse gas emissions, marine eutrophication potential and land use, quantified per tonne of liveweight mussels harvested. Note that land use only includes use of land area and not sea area. These three life cycle impact categories are expected to provide a useful, and potentially contrasting, picture of the environmental impact of farmed mussels, although the more local ecological potential impacts are not covered. The dependency on agricultural land use is, however, often used as an indicator of terrestrial biodiversity impacts. Invitations to participate in the project were sent out widely to mussel producers in all countries bordering the North Atlantic. To those that showed interest and willingness to share data, a data collection spreadsheet was sent which was followed up by online or face-to-face meetings, in which the production technique and the composition of a typical mussel rig in terms of material use and lifetime were discussed and quantified, as well as boat use and the fate of the biomass harvested. Data was collected for the period 2021-2024, indicating average, maximum, and minimum production conditions during that period. In this study, we want to analyse the relative contribution of the production of the mussel rig (i.e. the infrastructure) compared growout to total environmental impacts of on three farm sites across the Northeast Atlantic, using different farming technologies and strategies.

## Results

The length of the farming cycle of blue mussels differs between 10 and 24 months in the three locations analysed here (Table 1). Some producers let mussel spat settle naturally and let them grow until harvest size, others harvest and reseed the mussels on ropes after 3-4 months, to achieve higher growth, and more even size and quality of the mussels harvested. Fuel use was between 17-35 l/tonne mussels harvested, depending on the type and size of vessels used, whether mussels are only harvested once or twice to be reseeded, and the area over which each producer operates. On average, infrastructure stands for 11-54% of greenhouse gas emissions, 1-58% of marine eutrophication and 1-62% of land use (Fig. 1). Land use is dominated by the farming of cotton used in the cotton sock when reseeding as well as fuel production. Eutrophication is likewise dominated by manufacture of the cotton sock. Greenhouse gas emissions are instead dominated by fuel production and combustion.

## Discussion

Early results show that there are big differences in life cycle environmental impacts between and within locations and farming techniques, which opens up for improvements of already low-impact production systems. Fuel use of boats used in growout is the single most important contributor to greenhouse gas emissions in all systems, so efforts to reduce the fuel use, and shifting to alternative fuels, would help reducing farmgate emissions. One way to reduce the need for using boats, is if the rigs could be monitored digitally, and this kind of technology is currently being developed for low-trophic aquaculture. While there are indications that reseeding comes at the cost of higher fuel use (Frösell 2019), we cannot draw this conclusion here, since there are too many other factors that influence the fuel use in mussel farming. In coming years, data will be complemented, and the possibilities and tradeoffs connected to large-scale expansion of mussel farming will be mapped. If you are interested in collaborating, as a producer, researcher, or have questions about the project – feel free to get in touch!

## Introduction

Similar to what is witnessed in mammals, teleost fish present a network of immune, neural and endocrine signals enabling a delicate and efficient bidirectional communication between the central nervous system and the gastrointestinal tract. Among other processes, intestinal inflammation triggers a cascade of events that necessarily lead to this brain-gut axis activation, which will then unfold multiple regulatory mechanisms. In fish however, such intricate processes are poorly documented. Aiming at using fish brain-gut axis as an asset in nutritional health-enhancing strategies, it is imperative to fully grasp its most intrinsic dynamics. This preliminary approach intends to evaluate the outreach of a peripheral inflammatory process (enteritis) in activating central neuroendocrine mechanisms, focusing on gene expression changing patterns at both ends of the brain-gut axis

## Material and Methods

Juvenile rainbow trout (RT, 45 ± g), *Oncorhynchus mykiss*, were distributed in two, 300 l tanks, one group being fed a commercial diet and the other group the same commercial diet supplemented with dextran sodium sulfate (DSS, 1% dry matter) to induce acute enteritis. Fish were fed twice a day *ad libitum*, and were sampled at the end of 5- and 15-days feeding periods. Samples of hypothalamus, pituitary gland and anterior intestine were collected and processed for RNA extraction. A panel of immune and neuroendocrine molecular markers was carefully assembled and gene expression was measured by real time PCR. Moreover, transcriptomic (RNAseq) analysis was performed in the anterior gut samples by Illumina sequencing.

## Results

The expression level of immune-related genes such as cluster of differentiation 3 and 8 (*cd3* and *cd8*), aryl hydrocarbon receptor (*ahr*) and interleukin 1β (*ilβ)* was upregulated in RT gut fed DSS-supplemented diets for 15 days. Expression of the serotonin transporter *serta* was similarly increased in this group and tissue, and so was gene expression of the transmembrane protein *claudin*. Hypothalamic corticotropin-releasing hormone (*crh*) expression increased in fish fed DSS-supplemented diet for 15 days. No significant changes were observed among genes studied in the pituitary gland. In what the transcriptomic approach is concerned, while 5 days of DSS-feeding only slightly changed gene expression (a total of 22 differential expressed genes, DEGs), a 15-days feeding period more significantly affected gut transcriptomics (120 DEGs). Regarding the longer feeding period, the biological function digestion was enriched by several downregulated genes of enzymes such as trypsin and carboxypeptidase. In contrast, immune-related terms such as leukocyte proliferation and T-cell activation were found enriched by upregulated genes such as TSC22 domain family protein 3 isoform X1 (*tsc22*), Kruppel like factor 9 (*klf9*) and transforming growth factor beta activator (*lrrc3*).

## Discussion

The enhancement of immune cell markers (*cd3* and *cd8*) and inflammatory mediators (*il1β* and *ahr*) observed by real-time qPCR in the target tissue of the inflammatory model – the intestine – points to the successful implementation of an inflammatory dietary compound typically used in mammalian studies. As somewhat expected, serotonin dynamics seemed to be altered as well as denoted by the upregulated expression of its transporter. Such peripheral serotonergic changes stand as potential triggering mechanisms of central neuroendocrine activity. Indeed, at the hypothalamus level, expression levels of the first secreted hormone (CRH) were enhanced, representing a strong indication of the brain responsiveness to intestinal inflammatory conditions. In accordance with real-time qPCR analysis, intestine RNA sequencing of fish fed DSS-supplemented diet for 15 days depicts a state of immune activation and compromised digestion. However, no indication of changes to serotonin-related pathways was found among the observed DEGs.

*(Continued on next page)*

In conclusion, results point to DSS dietary administration as a promising enteritis model in RT. Despite no changes in serotonin dynamics were observed during the RNA-sequencing analysis in gut samples, the increased expression of related genes in both gut and brain tissues is an indication of brain responsiveness to gut inflammation.

## Introduction

Sex control and thus the understanding of sex determination and sex differentiation in fishes is crucial in aquaculture due, for example, to the need for controlling reproduction, producing monosex populations. The production of such populations is of particular importance owing to differences in growth rates or economical values of sexes in some species (Yamazaki, 1983). Various methods, including hormonal treatments, chromosomal manipulation, hybridization, and selective breeding, have been employed to achieve sex control in fishes (Wang et al., 2018). Besides these techniques, some studies reported that the use of electric shock can also influence sex ratios. For instance, Okomoda et al. (2020a) showed that applying electric shock to red hybrid tilapia (*Oreochromis mossambicus* × *O. niloticus*) resulted in a 70% male population. Electric shock has been widely used for triploid production in various species, including mussels (Cadorel, 1992), African catfish (*Clarias gariepinus*) (Okomoda et al., 2020b), tilapia (Hassan et al., 2018; Okomoda et al., 2020a), and coho salmon (*Oncorhynchus kisutch*) (Teskeredžić et al., 1993). The main objective of our study was to investigate the effects of an electric shock on the development of embryos of rainbow trout gonads varying the timing of the shocks after fertilization while avoiding the production of triploid populations. To do so we measured sex ratio and quantified, growth performance, and fatty acid composition that ultimately will affect the nutritional values for consumers.

## Materials and methods

Three male and five female rainbow trout (*Oncorhynchus mykiss*) were used for gametes collection. Fertilized eggs of rainbow trout were exposed to a direct electrical current of 12V for 10 minutes at different times post-fertilization (20, 30, and 40 minutes), using well water with different salinity levels (5ppt and 0ppt). The electric field was generated using a rechargeable battery connected to rectangular aluminium electric probes, placed 30 cm apart to match the container's cross-sectional area within a plastic container of 35x25x15cm. Nitrate, chloride, and carbonate/bicarbonate were also tested using standard methods. Analysis for potassium, magnesium, sodium, cobalt, barium, beryllium, bismuth, selenium, chromium, iron, nickel, copper, and calcium was performed following Method 200.7. Erythrocyte measurements were analysed to assess ploidy levels. Growth performance, live weight gain, survival rate, total feed intake, feed conversion ratio, and specific growth rate were calculated. Histological procedures were performed to identify the cell types involved in spermatogenesis or oogenesis; samples were stained with Hematoxylin-Eosin. The sex ratio was determined by histological examination of the gonads, with groups categorized based on electrical exposure post-fertilization. Fatty acids analysis was conducted in muscle and liver tissue using Gas Chromatography.

A two-sample t-test was used to compare fertilization rates between treatments. Fertilization and hatching rates, water parameters, growth performance, and fatty acid profiles were analysed using one-way ANOVA, followed by Tukey's post hoc test ($P < 0.05$). Ploidy determination was conducted using one-way ANOVA with Fisher's post hoc test ($P \leq 0.05$). All statistical analyses were performed using Minitab 18. Principal component analysis of erythrocytes was carried out in RStudio.

## Results

The results of the application of an electric shock at different post-fertilization times (20, 30, and 40 minutes) and salinity levels (0 and 5 ppt) did not significantly affect the fertility or hatching rates. Ploidy determination showed significant differences among treatments ($P \leq 0.05$); however, the values are consistent within the diploid range, reinforcing the conclusion that the observed characteristics are typical of diploid organisms. Groups shocked at 0 ppt salinity after 20-, 30- and 40-minutes fertilization showed greater values of cell-nuclear area ratio and cell-nuclear volume ratio to Principal Component 2, where the nuclear structure may be more affected by electric shock. Triploidy was not observed, as triploid individuals exhibited significantly larger cell and nuclear dimensions. Initial weights did not significantly differ among treatments ($P > 0.05$). However, significant differences were observed in final weight and total weight gain ($P < 0.05$). The highest final weight was

*(Continued on next page)*

recorded in the at 0 ppt salinity after 30 minutes fertilization (39.07 ± 0.08g), which was significantly higher than most other treatments. The sex ratio results showed no significant differences among the experimental groups or the control group ($P > 0.05$). Histological examination of gonads from the experimental groups and the control group showed no differences between the experimental and control groups regarding gonadal structure, both in males and females. No significant differences were observed in the overall proportions of saturated, monounsaturated, polyunsaturated, or total trans fatty acids in both muscle and liver, indicating that the electrical shock treatments did not alter the global balance of fatty acid groups. However, linoleic acid (C18:2) was significantly higher in the 20 minutes post-fertilization group compared to the control. Similarly, linolenic acid (C18:3) was significantly elevated in the 20- and 30-minutes post-fertilization groups relative to the control. Eicosapentaenoic acid (EPA, C20:5) was also significantly higher in the 30 minutes post-fertilization group compared to the control.

**Discussion and conclusions**

This study demonstrates that exposure to a 12V (voltage gradients 0.4 V/cm) for 10 minutes at different times (20, 30, and 40 minutes) after fertilization have no negative effects on fertility and hatching rates in rainbow trout embryos. Despite the relatively low voltage gradient, 12V electrical shock still induced significant developmental impacts, reinforcing the sensitivity of embryos during early developmental stages. No triploidy induction was confirmed, as erythrocyte characteristics remained consistent with diploid individuals. However, 12V electrical shock influenced growth performance and showed differences in specifics fatty acid profiles, possible due to metabolic stress rather than ploidy-related effects. Future research should investigate the combined effects of a 12V electrical shock with other environmental factors, such as temperature, oxygen levels, or salinity, to better understand their interactions and potential applications in aquaculture.

## Introduction

Reproductive success is a key determinant in aquaculture productivity, particularly in species of high commercial value such as rainbow trout (*Oncorhynchus mykiss*). In recent years, dietary probiotics have gained attention as promising functional feed additives to enhance reproductive parameters through improved immunity, nutrient absorption, and overall broodstock health (Abkari-Nargesi et al., 2020). Among the microbial candidates, *Lactococcus lactis* (Abkari-Nargesi et al., 2020) and *Hafnia alvei* (Didinen et al., 2016) have shown beneficial effects in various animal models. However, their specific influence on fish gamete quality and early embryonic development remains underexplored. In recent years, statistical modelling has been used in aquaculture to predict outcomes of dietary additives on growth and feed efficiency (Serradell et al., 2023; Qian et al., 2024). Statistical prediction based on fertilization outcomes offer a valuable statistical framework to estimate reproductive outcomes, such as hatching and eyed-stage success. This study aims to statistically evaluate the predictive power of fertilization rate on embryonic development stages under different probiotic treatments, using linear regression models.

## Materials and methods

This study was conducted using data from an experimental study of the project supported by TUBİTAK (Project No:222N019) to evaluate the effects of probiotic supplementation on gamete quality in rainbow trout (*O. mykiss*). The experimental diets were supplemented with two different probiotic bacterial species, each at two different concentrations. The probiotic bacteria used in the study were *Hafnia alvei* (P10) and *Lactococcus lactis* (P9), at two concentrations $10^7$ (C1) and $10^9$ (C2) CFU $g^{-1}$. First, the effect of the two different bacterial species was analysed regardless of their concentration. Second, the effect of the bacterial concentration was evaluated regardless of the bacterial species. Fertilization, eyed-staged and hatching rate were measured for a simple linear regression model in order to analyse the relationship between fertilization rate (independent variable) and either eyed-stage or hatching rate (dependent variable). The analyses were performed using RStudio 4.4.1. The outputs included predicted values, 95% confidence intervals, correlation coefficient (R) and coefficient of determination ($R^2$), where the formula (*Estimated outcome* = $\beta 0 + \beta 1$ *x Fertilization Rate*). These metrics were used to evaluate the predictive strength of fertilization rate on eyed-stage and hatching success, and to compare model performance across different probiotic treatments.

## Results

The fertilization and eyed-stage rate parameters for rainbow trout used in the experiment showed the following correlation coefficients: 0.99 for the low-concentration C1 group and 0.95 for the high-concentration C2 group. Coefficients of determination ($R^2$) were found to be 99.93% for the C1 group and 90.76% for the C2 group. The fertilization and hatching rate parameters showed the following correlation coefficients: 0.77 for the low-concentration C1 group and 0.79 for the high-concentration C2 group. Coefficients of determination ($R^2$) for the fertilization rate and eyed-stage rate were found to be 55.95% for the C1 group and 62.79% for the C2 group. By using different probiotic bacterial strains, the correlation coefficients between fertilization and eyed-stage rates were 0.99 for the P10 bacteria group and 0.93 for the P9 group. The determination coefficients were 99.58%

*(Continued on next page)*

for P10 and 86.72% for P9. The correlation coefficients between fertilization and hatching rates were 0.75 for the P10 bacteria group and 0.79 for the P9 group. The determination coefficients were 55.78% for P10 and 66.06% for P9.

**Discussion and conclusions**

This study has focused on statistical predictions of the effects of probiotics additives on gamete quality of rainbow trout. Our results suggest that while the lower dose (C1) supports more consistent embryonic development (eyed-stage), the higher dose (C2) may be more effective in enhancing hatching success. Mathematical modelling has been recognized as an effective method for evaluating the relationship between physiological and environmental parameters in fish, considering different variables (Qian et al., 2024). Serradell et al. (2023) have reported that using a multiple linear regression model in *Dicentrarchus labrax*, probiotics added to feed explained 67%, 80%, and 63% of the variation ($R^2$) in specific growth rate (SGR), feed conversion ratio (FCR), and feed intake (FI), respectively. However, the model showed that the probiotics obtained values did not have a significant influence on the predicted outcomes. In this study, statistical analyses indicate that P9 has a higher predictive association with hatching success, while P10 showed a more consistent predictive relationship with the development of embryos to the eyed stage. These patterns were also supported by high correlation and determination coefficients, particularly for the fertilization and eyed-stage rates in the C1 and P10 groups. Furthermore, statistical prediction confirmed the stronger reliability of these relationships in lower probiotic concentrations and with the P10 strain, supporting their potential for improving reproductive success in rainbow trout.

# THE ROAD TO BECOMING THE WORLD'S LEADING *Acartia tonsa* PRODUCER

L. Baardsgaard*, T. Remman

linn@cfeed.no

## Introduction

Plankton production, particularly copepods (*Acartia tonsa*), represents one of aquaculture's most complex biological challenges. Their fragility, sensitivity to environmental change, and complex life cycle have made industrial-scale production difficult to achieve.

## From Start-up to Industrial Scale

After several years of persistent effort, CFEED has achieved robust, industrial production of copepods. Transforming from a promising start-up into the first large-scale copepod producer required more than simply scaling laboratory processes. Achieving consistent product quality and yield at a commercial scale demanded careful optimization of production conditions and parameters. This presentation will chronicle our journey: from the initial scientific and operational challenges in mass copepod cultivation, through strategic pivots that redefined our processes, to the key technological innovations that enabled us to scale efficiently, sustainably, and with strong biosecurity.

## Overcoming Market and Regulatory Challenges

We will share how we overcame significant market entry barriers, such as ensuring consistent biomass quality and meeting strict regulatory standards, while building a resilient company culture based on science and environmental stewardship. Our approach leverages key innovations: advanced bioreactor technology, controlled production systems, a newly designed reproduction program, and data-driven optimization to streamline operations and minimize environmental impact.

## Environmental Impact and Feed Efficiency

A central outcome of these innovations is the long-term improvement of feed conversion ratio (FCR) in aquaculture species, reducing the overall need for feed. This is especially significant because approximately 70% of aquaculture's global $CO_2$ emissions are linked to feed production. By improving FCR and lowering feed demand, our solutions directly contribute to reducing the carbon footprint of the industry and advancing more sustainable aquaculture practices.

## Conclusion and Insights

Attendees will gain actionable insights into the critical success factors behind long-term scaling in the blue biotech sector, including continuous innovation. Our story offers valuable lessons for organizations seeking to break through growth plateaus and achieve lasting impact in sustainable aquaculture. By sharing our experience, we aim to contribute to the ongoing dialogue on sustainable plankton production and provide examples for others facing similar scaling challenges.

BIVALNET is a research network established in 2023, dedicated to study and promote the ecosystem services provided by bivalves. Coordinated by the IIM-CSIC, the network brings together researchers from the University of Cádiz (UCA), University of Vigo (UVIGO), University of the Basque Country (UPV/EHU), the Oceanographic Centres of Murcia, Cádiz, and Vigo (IEO-CSIC), the Torre de la Sal Aquaculture Institute (IATS-CSIC), and the Institut de Ciències del Mar (ICM-CSIC).

Figure 1. Map showing the institutions that are currently part of Bivalnet network.

*(Continued on next page)*

The objectives of BIVALNET include, among others: (i) fostering long-term collaboration among the network's research groups; (ii) integrating scientific knowledge across disciplines to enhance the understanding and promotion of bivalve ecosystem services; (iii) establishing protocols for joint use of research equipment and infrastructure; (iv) promoting the mobility of trainees and early-career researchers; (v) facilitating knowledge transfer between research groups and supporting the development of new collaborative projects; (vi) raising public awareness about the goods and services provided by bivalves; (vii) encouraging the advancement and dissemination of bivalve-related research; (viii) supporting public policy development that benefits bivalve aquaculture and the restoration of bivalve populations; and (ix) strengthening relations with international organizations focused on the recovery of wild bivalve populations and their associated ecosystem services.

Several groups within the network are actively engaged in research on the use of the flat oyster (*Ostrea edulis*) for bioremediation and restoration purposes. In addition, BIVALNET seeks to broaden its scope by integrating knowledge on other bivalve species and involving research groups not yet part of the network but who share its core objectives. This expansion aims to strengthen multidisciplinary collaboration and advance the collective understanding of the ecosystem services provided by bivalves.

BIVALNET is funded by Spanish State Plan for Scientific, Technical and Innovation Research 2021–2023 to "Research Networks". Reference: RED2022-134186-T of MICIU/AEI/10.13039/501100011033.

# MONITORING ENVIRONMENTAL INTERACTIONS OF MARINE AQUACULTURE IN ALGERIA: INSIGHTS FROM THE DZAQUAFARM PROJECT

S. Bachouche[1], A. Inal[1], S. Amalou[2] and S. Grimes[3]

[1] National Center for Research and Development in Fisheries and Aquaculture, Algeria
[2] National Laboratory for the Control and Analysis of Fishery and Aquaculture Products and Environmental Health
[3] National Higher School of Marine Sciences and Coastal Management, Algeria
Email: bachouche.samirl@gmail.com

Marine aquaculture in Algeria is experiencing rapid growth, driven by increasing demand for seafood and the need to diversify economic activities in coastal regions. However, this expansion poses significant environmental challenges, including water quality degradation, habitat alteration, and interactions with marine ecosystems. The DZAquaFarm project addresses these challenges by implementing an integrated environmental monitoring system for marine aquaculture sites across Algeria.

The project combines in-situ measurements and remote sensing data to monitor key environmental parameters, such as oceanographic conditions, phytoplankton dynamics, and ecotoxicological indicators. These data are integrated into a Geographic Information System (GIS) and visualized through an interactive webmapping platform. This system enables real-time monitoring of aquaculture sites and provides stakeholders with actionable insights into the environmental status of marine farms.

Preliminary results highlight the variability of environmental conditions across aquaculture sites, with some areas showing signs of eutrophication and increased susceptibility to harmful algal blooms. The project also identifies sensitive coastal zones where aquaculture activities may exacerbate anthropogenic pressures. A classification system has been developed to label aquaculture farms based on their environmental performance, promoting best practices and sustainable management.

By providing a comprehensive understanding of the interactions between aquaculture and the marine environment, the DZAquaFarm project supports evidence-based decision-making for sustainable aquaculture development. The platform also serves as an early warning system for environmental risks, such as toxic phytoplankton blooms, enhancing the resilience of the aquaculture sector in Algeria. This approach demonstrates the importance of integrated monitoring systems in balancing economic growth with environmental conservation in Mediterranean coastal regions.

# MEDITERRANEAN PRAWN (*Penaeus kerathurus*) AS POTENTIAL EXPLOTAIBLE SPECIES IN MEDITERRANEAN AQUACULTURE

A. Badajoz-Rodriguez* N. Casado-Coy, V. Fernandez-Gonzalez, Tomas Conde Crespo

Department of Marine Sciences
University of Alicante
Carretera San Vicente del Raspeig s/n, 03690, Alicante, Spain
E-mail: alba.badajoz@gcloud.ua.es

**Introduction**

According to the European Union (EU) strategic guidelines (COM/2021/236 final), the long-term sustainability of the aquaculture sector passes through both the diversification of species and implementation more environmentally friendly systems. Thus, the share of farmed crustacean has risen over time and nowadays they are in second position of the global trade in aquatic animal products in 2022, making up 23 percent of the total value (FAO, 2024). *Penaeus (Melicertus) kerathurus* (Forskål, 1775) is a benthic species native to the Mediterranean Sea and the eastern Atlantic Ocean, with a distribution range extending from the coasts of Portugal to Angola (Zitari-Chatti et al., 2008). During the 1970s, *P. kerathurus* was considered a promising candidate for intensive aquaculture in southern Europe, however, several issues reduced its commercial exploitation in favor of other species. Despite its economic and ecological significance, knowledge regarding the species' biology remains limited, and data on population structure are scarce. This lack of information hinders the development of effective cultivation methods for commercial purposes. The present study seeks to expand our understanding of the biology and ecology of *P. kerathurus*, with the aim of establishing an optimal and economically viable aquaculture methodology.

**Materials and Methods.**

In this work, a comprehensive literature search about *P. kerathurus* was conducted, focusing on enabling its cultivation under controlled conditions and ultimately achieving full life cycle closure in captivity. In addition, data from both extractive fishing activity and fattening practices in recent decades were obtained from the official website of the Ministry of Agriculture, Fisheries and Food of the Government of Spain. Literature review carried out using the electronic databases Scopus and PubMed to identify relevant scientific publications on the biology and ecology of the species. For this, *'Penaeus (Melicertus) kerathurus'* AND *'aquaculture'* were used as keywords, restricting publication time between 1980 and 2024. Initial screening focused on studies addressing the species biology and ecological characteristics. Subsequently, a more refined search was conducted to identify literature related specifically to breeding techniques and captive rearing practices attempted to date. Articles were selected based on their relevance to the scope of the review, prioritising those that presented empirical findings, practical methodologies, or reviews of aquaculture strategies applicable to the target species.

**Results and Discussion**.

At present, the culture of *P. kerathurus* in countries such as Spain is confined to the fattening phase within coastal lagoon systems (Figure 1).

Studies confirm that specific environmental conditions are required, such as a salinity range between 28–35 for reproduction and larval development, although standardised protocols for captive breeding remain underdeveloped. Experimental trials have achieved partial success in broodstock conditioning and early-stage larval rearing, but survival rates remain inconsistent. Major limitations include the scarcity of long-term studies and fragmented data across regions. Despite these gaps, current evidence supports the feasibility of closing the species' life cycle in captivity with further targeted research. Contemporary technological advancements in system design and intra-family nutrition (FAO, 2022) present renewed opportunities to critically reassess its agricultural potential.

# INTERACTIVE EFFECTS OF SALINITY AND DIETARY IRON ON ω3 LC-PUFA BIOSYNTHESIS IN *Platynereis dumerilii*

Khalida Bainour*[1], Óscar Monroig[1], Florian Raible[2], Leonie Adelmann[2], Juan C. Navarro[1]

**Introduction**

Polychaetes are promising sources of ω3 long-chain ($\geq C_{20}$) polyunsaturated fatty acids (LC-PUFA) due to their ability to synthesise these essential nutrients through the action of fatty acyl elongases (Elovl), front-end desaturases (Fed), and methyl-end desaturases (ω-des) (Monroig et al., 2022). It has been suggested that salinity can influence lipid metabolism in aquatic invertebrates, as it triggers osmotic stress that alters membrane lipid composition (Palacios and Racotta, 2007). Iron also plays a crucial role in lipid metabolism and, among other functions, iron is a cofactor of desaturase enzymes like Fed and ω-des involved in LC-PUFA biosynthesis (Shanklin et al., 2009). We hypothesize that salinity conditions leading to increased expression of Fed and/or ω-des will only result in increase desaturase activity and ultimately LC-PUFA biosynthesis, if iron supplementation ensures full activation of the desaturase enzyme pool. To test this hypothesis, this study investigated (i) the effects of salinity on fatty acid profiles and expression of genes involved in the ω3 LC-PUFA synthesis in the marine polychaete *Platynereis dumerilii*, and (ii) the combined effects of salinity and dietary iron on the *P. dumerilii* LC-PUFA biosynthesis.

**Materials and Methods**

Two *in vivo* trials were conducted using *P. dumerilii* juveniles maintained under standard conditions (18 °C, 16L:8D photoperiod; low-PUFA diet). Trial 1 assessed the effects of three salinity levels (30‰, 35‰, and 40‰), using three plastic boxes per salinity level, each containing 16 worms. In Trial 2, *P. dumerilii* were reared under four conditions combining two salinities (35‰ and 40‰) and two diets (with or without iron supplementation), using four plastic boxes per condition, each with 25 worms. At the end of each trial, samples were collected to evaluate the effects on the ω3 LC-PUFA biosynthesis through fatty acid profiling, and gene expression analysis of key desaturases and elongases of the *P. dumerilii* LC-PUFA biosynthesis. Principal Component Analysis (PCA) was conducted to explore patterns in fatty acid profiles and assess potential differences among treatments.

**Results**

For Trial 1, *P. dumerilii* exhibited elevated levels of ω3 LC-PUFA, specifically eicosatetraenoic acid (20:4n-3), eicosapentaenoic acid (20:5n-3), and docosapentaenoic acid (22:5n-3) at 40‰ salinity, compared to individuals maintained at 35‰ and 30‰, despite receiving the same diet. Gene expression analysis revealed a significant upregulation of the *P. dumerilii* Δ6/Δ8 Fed desaturase under high salinity (40‰), accompanied by a decrease in its metabolic substrates (20:2n-6 and 20:3n-3); these results indicate an enhanced desaturase activity at high salinity. In Trial 2, PCA of the fatty acid profiles showed a clear separation among the four experimental groups. The first component distinguished salinities, and the second separated diets with and without iron supplementation, especially at 40‰ salinity (Fig. 1). No effects from iron supplementation were observed at 35‰ salinity. Notably, at 40‰, iron supplementation correlated with increased levels of 20:3n-6 and 20:4n-3 (Fig. 1), both desaturase products from the *P. dumerilii* Δ6/Δ8 Fed and therefore supporting enhanced desaturase activity. These results support the conclusion that the ω3 LC-PUFA biosynthesis in *P. dumerilii* is influenced by both salinity and dietary iron. The proposed mechanism involves an upregulation of fatty acyl desaturases at high salinity, while iron supplementation guarantees the enzymatic activity that leads to enhanced LC-PUFA biosynthesis and improved nutritional value.

# BY-PRODUCTS VALORIZATION OF AFRICAN CATFISH (*Clarias gariepinus* BURCHELL, 1822)

Laura Ballesteros-Redondo[a,*], Adrian Bischoff-Lang[a], Harry Palm[a]

[a]University of Rostock, Faculty of Agricultural and Environmental Sciences, Department of Aquaculture and Sea-Ranching, Justus-von-Liebig-Weg 6, 18059 Rostock, Germany.

## Introduction

In the context of advancing a blue and circular economy, utilizing the full potential of African catfish (*Clarias gariepinus* Burchell, 1822) by-products—specifically the liver, gonads, and skin—can significantly reduce waste and enhance resource efficiency. While considerable research has focused on the nutrition (Langi et al. 2024) and nutritional content of the fillets, there remains a notable gap in understanding the potential applications of the catfish's liver, gonads, and skin. Research shows that the liver of African catfish is rich in polyunsaturated fatty acids (PUFA) and has low concentrations of triglycerides and saturated fatty acids (SFA), particularly when the fish is fed high-protein diets (Matter et al. 2004, Taiwo et al. 2014).

The study aimed to unravel the composition of fatty acids of by-products of the African catfish within a Recirculating Aquaculture Systems (RAS) and the most suitable moment for harvesting to maximize the use of nutrients and their further potential reuse.

## Material and methods

We monitored the growth in total body weight, the hepatosomatic index (HSI), the gonadosomatic index (GSI), the skin weight and the filet weight (without the skin) of African catfish. Furthermore, the content of fatty acids in the liver, gonads and skin was analysed.

## Results

**Table 1.** Total body weight, HSI, GSI, skin and meat percentages over the total body weight of African catfish at 5 different samplings (each 3 weeks) in RAS

# LIGHT SPECTRUM, TEMPERATURE AND FEEDING REGIME EFFECT ON RAINBOW TROUT (*Oncorhynchus mykiss*): WELFARE AND PHYSIOLOGICAL RESPONSES

A. Barany*, L. Herrera-Castillo, M.J. Delgado, T. González-Rodríguez, M. Gómez-Boronat, N. de Pedro, and E. Isorna

Fish Neuroendocrinology Research Group

## Introduction

Rainbow trout (*O. mykiss*) production in Europe accounts for approximately 20% of global production, making it the most farmed freshwater species. To optimize both economic efficiency and animal welfare, three key parameters were studied: temperature, light spectrum, and feeding regime. Temperature is a crucial factor affecting fish metabolism, growth, respiration, stress, and reproduction [1]. Light spectrum, as previous studies indicate that blue and green wavelengths can optimize growth performance in some teleosts [2,3]. Feeding regime is another vital parameter. A fixed feeding schedule that allows fish to anticipate food arrival, can impact growth and metabolism [4]. Proper feeding practices ensure that the fish receive adequate nutrition and maintain optimal health.

## Materials and methods

Juvenile trout (3,7±0,3 g weight and 6,7±0,2 cm length) were homogeneously distributed into eight independent experimental groups by duplicates, with different rearing conditions by combining different temperatures (15 or 20ºC), light spectrum [white 380-750nm (W); green 495-570nm (G); or blue 450-494nm (B)] and feeding regime (SF or RF, scheduled or random feedings, limited to white light and at 15ºC). The following experimental groups were established: 15_W_SF; 20_W_SF; 15_G_SF; 20_G_SF; 15_B_SF; 20_B_SF; 15_W_RF; 20_W_RF. During the experimental period, fish were reared under a 12D:12L photoperiod and daily fed at 3% of body weight. After 35 days, black-white preference tests were performed to assess anxiety-like behavior and blood samples were taken to measure cortisol. At the end of the experimental period (45 days), ten fish per treatment were euthanized with a lethal dose of MS-222 (400 mg/L) to collect hypothalamus and liver for RNAseq analysis focusing on genes related to stress, energy balance and photoreception. In addition, another group of fish for each treatment was sacrificed during a 24-hour period (every 4 hours) to sample blood, hypothalamus, pituitary and head kidney to measure cortisol and clock gene expression daily rhythms. Lastly, *ex vivo* skin explants from dorsal and ventral regions were examined to assess permeability to absolute irradiance (EI) with a spectroradiometer.

## Results and discussion

Temperature was the only condition that significantly increased plasma cortisol levels (Figs. 1A, 2A). This effect was not observed in fish reared under G or B lights, or under W light between SF or RF, possibly due to already elevated basal cortisol levels. Overall, fish exposed to 20ºC tend to exhibit longer latency to enter the aversive white area in the black-white preference tests and spend less time in it (Figs. 1B,C and 2B,C), suggesting increased anxiety under such conditions. Interestingly, at 20ºC, time spent in the aversive white area was diminished in fish under G compared to W; B presented intermediated values (Figs 1C). Remarkably, G light and RF condition did not highlight differences between 15 and 20ºC indicating already heightened anxiety. We confirmed the lights spectrum (Fig. 3A) and characterized skin permeability to absolute irradiance (EI) under each treatment. For the dorsal region, B light significantly increased EI permeability (Fig. 3B), whereas the ventral region showed reduced EI permeability (Fig. 3C).

In summary, our study shows that temperature is the primary factor significantly elevating plasma cortisol levels and anxiety-like behavior in rainbow trout, indicating heightened stress responses. Our findings underscore the complex interplay between environmental factors and fish welfare, highlighting the need for tailored aquaculture practices to optimize physiological and behavioral health in this species.

## Introduction

Sea lamprey (*P. marinus*) populations across Europe—and particularly the Iberian Peninsula—are currently in sharp decline and classified as vulnerable due to overfishing, estuarine pollution, dam and canal construction, and riverbed gravel extraction, leading to local extirpations in many river systems. Today, lampreys are encountered only sporadically and seasonally (January–April), yet their cultural and gastronomic significance persists in Galicia (Spain), North Portugal and Bordeaux (France). Arbo's annual *Festa da Lamprea* drew over 35,000 visitors in 2023, while North Portugal's Penacova, Gondomar, and Entre-os-Rios host lamprey-themed weekends, and Bordeaux honors *lamproie à la bordelaise* with seasonal tastings—festivals that underscore both the lamprey's culinary appeal and its cultural importance, highlighting the urgency of conserving sea lamprey populations. The anadromous life cycle of *P. marinus* comprises a freshwater, filter-feeding larval stage; a parasitic juvenile stage—characterized by hematophagous micropredation—during downstream migration and marine residency; and a spawning adult phase upon return to rivers. We have a better understanding of the larval and adult stages in rivers, compared to the juvenile phase in the ocean, particularly its feeding physiology which remains understudied. In this pilot investigation, we evaluated the feasibility of captive rearing and developed a preliminary fattening protocol in which juveniles feed non-lethally on live Atlantic salmon (*Salmo salar*).

## Materials and methods

Juvenile sea lamprey (*P. marinus*; n = 35; 3.9 ± 0.8 g; 14.4 ± 0.9 cm) were intraperitoneally PIT tagged for individual tracking, then used in two independent feeding trials conducted May–August 2022. To benchmark against natural development, we maintained a fasting control group in fresh water (FW), mimicking the pre-feeding juveniles' stage. In Phase 1, lamprey were directly transferred to FW, brackish water (BW; 10–15‰), or SW (30‰) and held in single-tank replicates under each salinity for 30 days—each tank containing four Atlantic salmon (*S. salar*; 310.4 ± 38.7 g; 30.7 ± 1.1 cm) as live hosts, replaced whenever more than four lampreys attached to a fish or, if that threshold wasn't reached, weekly to prevent host mortality (replaced salmon recovered after exchange). In Phase 2, a separate cohort was held in two replicate tanks of BW for 39 days under the same four-salmon-per-tank and replacement protocol. Note that for all experiments, at least a 33% water exchange was performed weekly to maintain water quality, with additional exchange conducted whenever water clarity declined. Throughout both phases we tracked survival, attaching frequency (as a proxy for feeding behavior), and growth performance. At the end of Phase 1, all lamprey—including the FW fasting controls—were euthanized with a lethal dose of MS-222 (400 mg $L^{-1}$ buffered with $NaHCO_3$, pH 7) to collect hematocrit, plasma, gill, liver, caudal kidney, muscle, and proximal and distal intestine samples to characterize physiological status among groups. Additionally, liver and intestine morphometrics were recorded in relation to each fish's body mass.

## Results and discussion

In Phase 1 (Figs. 1A, B), salinity emerged as the key determinant of juvenile sea lamprey performance, with FW survival plummeting to 0% by day 20 due to complete mortality, whereas BW and SW sustained survival rates of 70% and 65%, respectively (Fig. 1A). Attachment to hosts commenced within the first 15 to 17 days across all salinities, achieving day 17 frequencies of ~10% in FW (prior to mass mortality); day 15 ~40% in BW, and days 15-17 ~50% in SW (Fig. 1B), underscoring the positive influence of elevated salinity on both survival and feeding initiation. Phase 2 (Figs. 1C, D) corroborated these trends: under BW, survival remained above 70% (Fig. 1C), while host-attachment frequency peaked at over 80% and feeding behaviour was evident from the experiment's outset (Fig. 1D).

*(Continued on next page)*

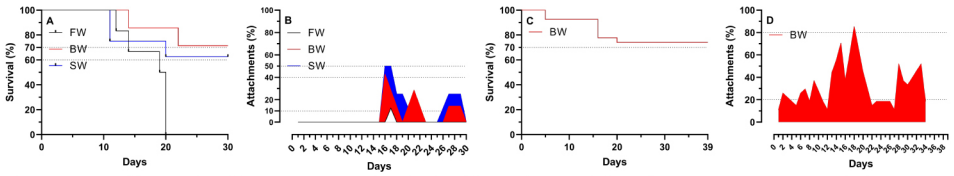

**Figure 1.** Effect of salinity on survival (A, C) and attaching frequency to host fish (B, D) on juvenile sea lamprey feeding trials. Figs.1A, B correspond to Phase 1, while Figs. 1C, D to Phase 2.

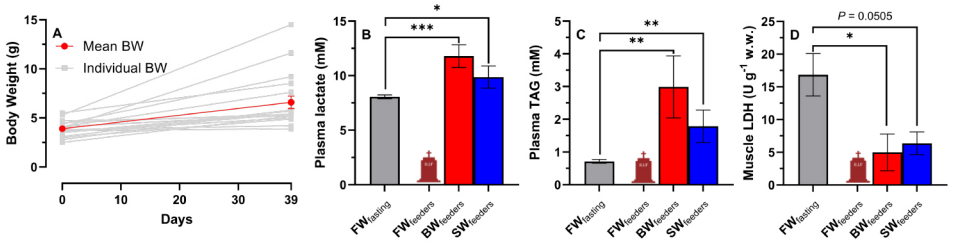

**Figure 2.** Growth performance in BW (A); plasma lactate (B), triglycerides (C), and muscle LDH (D). Fig.1A correspond to Phase 1, while Figs. 1B-D to Phase 2. ( ) indicates 100% mortality.

Post-feeding, juvenile lamprey showed high individual variability in growth performance but, overall, displayed substantial growth potential (on average, ~0.1 g per day; Fig. 2A), consistent with molecular data from the same individuals indicating active growth-related gene expression [1]. Plasma lactate levels rose significantly after feeding, mirroring the increase observed in plasma triglycerides (Figs. 2B, C). The surge in triglycerides indicates enhanced lipid uptake and storage following the exogenous nutrient supply. In contrast, muscle lactate dehydrogenase (LDH) activity declined markedly (Fig. 1D), likely reflecting a downregulation of glycolytic flux in muscle tissue as circulating nutrients became available.

In summary, our study indicates that salinity changes significantly enhance feeding and growth in juvenile sea lamprey. High survival and rapid host attachment occurred in individuals reared in BW and SW, while prolonged FW exposure led to mortality. This is the first comprehensive use of physiological analyses, supported by gut-content data, to confirm post-feeding status—showing strong growth, elevated plasma lactate and triglycerides, and reduced muscle LDH activity, signaling a shift to lipid metabolism. These results highlight the link between salinity, feeding, growth, and metabolism, and underscore the need for gentle handling, good water quality, and proper acclimation to maintain natural behaviors in captivity. Incorporating juvenile cultivation into full-cycle aquaculture could ease pressure on wild stocks, enable off-season supply and restoration efforts, and provide a consistent source for research—while ensuring host fish recover fully within a month.

**Introduction**

Alongside with the growing global aquaculture, shellfish aquaculture has also been increasing over the last years, with oysters and clams representing more than half of the world's production [1]. Bivalve farming is usually carried out in cages or structures placed in natural environments, such as estuaries or other coastal areas. Despite the benefits of this type of aquaculture, including the ability to improve water quality and provide several ecosystem services, it faces a major challenge called biofouling [2]. Biofouling is the development of undesirable species, such as seaweeds and invertebrates, on the surface of submerged farm structures, or even on the surface of the cultivated shellfish, representing a large constrain to marine aquaculture by reducing water flow, competing for resources and, therefore, negatively impacting productivity. Biofouling management represents an economic cost of 5-10% in the marine aquaculture industry [3], however, its prevention is essential to achieve efficient productions. While strategies such as physical cleaning, biocidal coatings (some of them toxic to non-targeted organisms), and genetic selection are being employed [3], there is an urgent need for the development of more sustainable approaches, as well as comprehensive assessments of their ecological impacts.

This research group has been investigating natural antifouling alternatives, such as the use of bioactive compounds [4], some derived from cyanobacteria [5, 6]. The aim of the present study was to assess the impact of four nature-based potential antifouling products on a commercially relevant clam species, *Venerupis corrugata*.

**Methods**

*V. corrugata* juveniles were acclimated for 4 days and, after that, they were exposed to cyanobacteria bioactive compounds (portoamides; **PA**) [5], two nucleosides (hypoxanthine arabinoside (**HA**) and 2'-deoxyinosine (**DOI**) (unpublished data)), and a nature-inspired polyphenol (**GBA26**) [7] for 48h, at six different concentrations: 6.25; 12.5; 25; 50; 100; 200 µM. To perform the assay, 12-well plates were filled with filtered seawater (17ºC) and 5 clams per well and three wells per treatment were used. A negative (seawater) and positive ($CuSO_4$; 5 µM) controls were also added. Mortality was regularly checked and according to these preliminary results, the most suitable concentrations were chosen to perform a second trial. The tested concentrations were 6.25; 12.5 and 25 µM and six clams per well and five wells per treatment were used. After 48h of exposure, live clams were collected for oxidative stress analysis. Whole tissue was homogenized in pools of 5 clams and lipid peroxidation (LPO), total protein content and the activities of catalase (CAT), superoxide dismutase (SOD) and glutathione-*S*-transferase (GST) were assessed.

**Results and Discussion**

Results demonstrated that after 48h, **DOI** and **GBA26** induced no mortality across all tested concentrations (up to 200 µM). In contrast, **PA** showed a dose-dependent increase in mortality, reaching approximately 85-90% at 200 µM, indicating acute toxicity only at very high concentrations.

The evaluation of oxidative stress biomarkers provided further insights. Results demonstrated no significant differences in total protein content, CAT, or GST activities across treatments, suggesting that these compounds did not induce significant metabolic disruption or detoxification responses. However, a significant increase of SOD activity was observed with the highest tested concentration of **DOI** (25 µM) and in the presence of **GBA26** and **PA** (at all concentrations) ($p$-value $\leq 0.01$ to $\leq 0.0001$). This suggests that these compounds, particularly at higher concentrations, can induce an oxidative stress response in *V. corrugata* juveniles, promoting the partial activation of the first-line antioxidant defence mechanism. LPO levels showed no significant differences after treatments, suggesting that the compounds did not cause oxidative cellular membrane damage.

*(Continued on next page)*

These findings underscore the importance of thoroughly evaluating the environmental safety of antifouling compounds, particularly in relation to their effects on the target farmed shellfish species. Antifouling formulations should be carefully designed to minimize potential adverse impacts on aquaculture organisms such as *Venerupis corrugata*. Future long-term and field-based studies will be essential to confirm the suitability and ecological safety of these nature-based solutions for practical use in shellfish aquaculture.

# LIFE CYCLE ASSESSMENT AND ENVIRONMENTAL RETURN ON INVESTMENT OF THE DIETARY SUPPLEMENTATION OF LYSO-PHOSPHOLIPIDS IN SHRIMP FEED

G. Bardera*[1], M. Dehasque[1], D. Militello[1], W. G. Nuez-Ortín[1].

[1]Adisseo, France.
Email: guillermo.bardera@adisseo.com

## Introduction

Shrimp feed formulation requires increasing flexibility and cost-efficiency while minimizing environmental impact. Lyso-phospholipids (LPL) are functional additives that support this goal by enabling partial ingredient replacement without compromising nutritional performance. This study assessed the net environmental benefit of a lyso-phospholipid-based additive (Aqualyso) in shrimp feeds through Life Cycle Assessment (LCA) and Environmental Return on Investment (EROI) analyses.

## Material and methods

LCA was conducted in accordance with ISO 14040/44 standards (ISO, 2006a,b), the Product Environmental Footprint Category Rules (PEFCR) guidelines (European commission, 2021), and FAO LEAP recommendations (FAO, 2020). Biological performance data from controlled trials testing the additive with *Litopenaeus vannamei* were used to simulate commercial shrimp farming in Indonesia. System boundaries included feed ingredient sourcing, feed processing, transport, on-farm emissions, and energy consumption. Carbon footprint (CFP) was calculated at both the feed level and farm level, expressed as kg $CO_2$eq/kg feed or $CO_2$eq/kg liveweight of shrimp, respectively, as the functional unit. Additionally, the EROI was assessed as the ratio between the reduction in CFP at the farm level and the environmental impact associated with the production of the additive (Blonk *et al*., 2021).

## Results & conclusions

Across all tested scenarios, the inclusion of Aqualyso in reformulated feeds led to measurable CFP reductions at both feed and farm levels, while delivering a positive EROI. In Scenario 1, 0.75% soy lecithin was replaced with 0.1% Aqualyso , resulting in CPF reductions of 2% and 8% at feed and farm levels, respectively (Fig. 1A). The corresponding EROI was 66 kg $CO_2$eq saved per kg $CO_2$eq produced by the additive. In Scenario 2, 1% soy lecithin was replaced with 0.05% Aqualyso, resulting in CFP reductions of 5% and 14% at feed and farm levels, respectively, (Fig. 1B), and in an EROI of 234 kg $CO_2$eq. In Scenario 3, 0.75% of soy lecithin and 0.5% of fish oil were replaced with 0.1% Aqualyso, leading to 3% and 15% reductions in feed and farm CFP, respectively l (Fig. 1C), and to an EROI of 115 kg$CO_2$ eq.

In all scenarios, soybean meal remained the primary contributor to feed-related emissions (35-55%; Fig. 1). Aqualyso enabled reductions in soy lecithin content, thereby marginally lowering overall feed emissions. The observed CFP reductions at the farm level were driven by improvements in feed conversion ratio and growth rate. These findings demonstrate that Aqualyso contributes meaningfully to the sustainability of shrimp production through improved feed formulation flexibility and reduced CFP emissions.

# A MARINE PROTEIN CONCENTRATE TO GAIN FLEXIBILITY IN THE FORMULATION OF FISH AND SHRIMP FEEDS

G. Bardera*[1], M. Dehasque[1], R. Robles-Arozarena[2], W. G. Nuez-Ortín[1]

[1]Adisseo, France
[2]Testing Blue S.L., Puerto Real, Spain

## Introduction

The development of sustainable and efficient feed additives is a major priority in aquaculture. Marine peptide concentrates, derived from high-quality marine ingredients, have emerged as promising ingredients due to their digestibility, balanced amino acid profiles, and potential functional benefits. However, species-specific responses and optimal inclusion levels must be carefully evaluated. This review summarises results from four feeding trials in three commercially important species, exploring the use of a marine peptide concentrate (Pepsea F) across different inclusion levels and diet formulations. Particular attention is given to the functional role of the additive in enhancing growth and feed efficiency under varying nutritional contexts.

## Material and methods

Four independent trials were conducted under controlled conditions using sea bream (*Sparus aurata*), catfish (*Clarias sp*.), and shrimp (*Litopenaeus vannamei*). Experimental diets were formulated with different fish meal (FM) levels (7%–20%), reflecting both reduced and moderate FM strategies. Pepsea F was incorporated at inclusion levels ranging from 0.4% to 2.6%, while the product was not used in control feeds. Husbandry and feeding protocols differed by species and life stage. Growth performance parameters including feed intake, weight gain, specific growth rate (SGR), feed conversion ratio (FCR), and survival were recorded and statistically analysed ($p < 0.05$).

## Results & conclusions

In Trial 1, sea bream fed a 10% FM feed supplemented with 2.6% Pepsea F for 10 weeks showed a significant 10% increase in feed intake, 12% improvement in growth, and 17% improvement in FCR relative to the control group.

In Trial 2, sea bream fed a 20%FM feed supplemented with 0.6% Pepsea F showed a significant 3% increase in feed intake and 4% improvement in growth after 11 weeks and compared to the control feed.

In Trial 3, catfish fed a feed containing 8% FM and 0.4% Pepsea F achieved a significant 10% higher feed intake, 3% greater growth performance, and 5% better FCR (not significant) after 8 weeks and in relation to the control feed.

In Trial 4, shrimp fed a 7% FM feed and supplemented with 0.5% Pepsea F over 7 weeks exhibited a significant 21% increase in feed intake and a numerically 3% improvement in growth in relation to the control group.

Overall, Pepsea F at both low (0.4 – 0.6%) and higher (2.6%) inclusion levels showed efficacy to improve the performance quality of a range of feed formulations and in different species. These trials demonstrate that Pepsea F can function as both palatability enhancer and performance booster and stands as an alternative to gain flexibility in formulation without compromising productivity.

# MORE THAN A PROTEIN SOURCE: MULTIFUNCTIONAL BENEFITS OF METHANOTROPH-DERIVED PROTEIN (FEEDKIND) IN FEED PROCESSING AND FISH HEALTH

G. Bardera*[1], E. Ooi[1], W. G. Nuez-Ortín[1].

[1]Adisseo, France.
Email: guillermo.bardera@adisseo.com

## Introduction

The rising demand for aquaculture production has intensified reliance on high-quality protein ingredients, particularly fish meal (FM), which remain nutritionally valuable but increasingly constrained by price volatility, limited supply, and ecological concerns. Alternative proteins from terrestrial animals and plants offer partial substitutions but often introduce variability in nutrient composition, anti-nutritional factors, or processing challenges that compromise feed efficiency and fish performance. Against this backdrop, methanotroph bacteria protein (MBP) produced from *Methylococcus capsulatus* through natural-gas fermentation, has emerged as a consistent and sustainable alternative. MBP is characterized by high protein content, favorable amino acid profile, excellent digestibility, and functional properties that influence both extrusion performance and fish physiology. Importantly, its production requires minimal agricultural land or water use, thereby reducing the environmental footprint compared with other alternative protein sources. Beyond replacing FM, MBP offers unique potential to improve feed processing efficiency and fish health condition at relatively low inclusion levels. This work synthesizes findings from three studies that assess the efficacy of the MBP-based FeedKind (FK, Adisseo) in improving feed processing efficiency and promoting fish health in commercial fish species.

## Material and methods

Th first study evaluated the applications of FK for feed production to improve the physical qualities of low-starch extrudates (Liu *et al*., 2023). The second study evaluated FK supplementation on growth performance and gut health of spotted seabass (*Lateolabrax maculatus;* Zhang *et al*., 2023). The third study investigated the effect of FK in largemouth bass ((*Micropterus salmoides*) to enhance antioxidant capacity and modulate the gut microbiome (Guo *et al.,* 2022).

## Results and discussion

The extrusion study demonstrated that the inclusion of 6% FK in 40% FM feeds reduced oil leakage by 35%, improved pellet expansion and durability by 4%. FK inclusion also lowered the required moisture level around 10% for conditioning, and 11% decrease in the temperature required in extrusion, these together reduced overall energy consumption of 37 kWh per ton of feed produced compared to the control feed. These conditions reduced drying time, water and energy use, contributing to more sustainable production of extruded feeds without compromising pellet quality.

Feeding trials further confirmed the functional health benefits of FK at relatively low inclusion levels. In Spotted seabass (3 g initial weight; 8 weeks duration), supplementation of 2% FK in high soybean meal content feeds (32% SBM, 28% FM) had a predominant role on cytokines regulation in the gut, alleviating soybean meal-induced enteritis. In largemouth bass (48 g initial weight; 10 weeks duration), 3-6% FK supplementation improved liver function as denoted by a decrease in plasma alanine aminotransferase concentration and improved antioxidant capacity in plasma and liver marked by a 32% and 30% increase of superoxide dismutase and by a 38% and 81% decrease of malondialdehyde concentration, respectively. Lastly, an increase in the beneficial microbial richness and diversity in the gut microbiome was also found in those groups fed FK.

## Conclusion

Collectively, these studies demonstrate that MBP-based Feedkind delivers consistent benefits beyond protein replacement. At low inclusion levels (2 – 6%), FK improves feed processing efficiency and promotes physiological resilience and gut health across fish species. These outcomes position FK as a multifunctional, sustainable protein source that can enhance both feed production efficiency and fish health in aquaculture.

## Introduction

For over 100 million years, the stable day-night cycle has driven the evolution of circadian clocks across different organisms, allowing them to anticipate and adapt to daily and seasonal environmental changes. In finfish, the circadian system regulates essential processes like digestion, cell proliferation, stress responses, and reproduction (Vallone et al., 2007). On the molecular level, the circadian clock genes (*clock, arntl, per, cry*) form the foundation of cellular time perception by generating rhythmicity through positive and negative transcription-translation feedback loops. While studies in typical model organisms, especially zebrafish, have shown early onset of circadian gene expression (Dekens & Whitmore, 2008), much less is known about this process in temperate commercial species such as Eurasian perch, a freshwater fish of significant ecological and aquaculture importance. Understanding when and how this mechanism becomes functional during early development is crucial, as it may enable adjustment of hatchery protocols for domesticated stocks (Cahill, 2002). This study aims to explore the development of the circadian clock in early life stages (embryos and larvae) of Eurasian perch, using high-resolution sampling. Relatively long period of embryogenesis and larval metamorphosis in Eurasian perch compared to species like zebrafish provided us with a unique opportunity to gain insights into circadian regulation of closely spaced developmental stages. Our objectives were to: (1) map the expression of core circadian genes at key developmental stages, (2) determine the onset of rhythmicity and compare it with other investigated species, and (3) explore the biological and aquaculture implications of our findings.

## Materials and methods

Eight families of Eurasian perch were created by controlled reproduction. Eggs were fertilized in vitro using cryopreserved semen (Judycka et al., 2022), and incubated in a recirculating aquaculture system (RAS) under a 14L:10D photoperiod, which simulates the natural light conditions during the spawning and early developmental stages of this species. The hatched larvae were reared in the same light conditions as embryos, until 36 days post hatching (DPH) following the standardized procedure (Palińska-Żarska et al., 2020).

Embryos and larvae were sampled continuously, every 4 hours, from the moment of fertilization to 3 DPH (11 days). From 3 DPH, larvae were sampled every 4 days, also in 4-hour intervals. The RNA from embryos and whole-larvae was extracted and analyzed for circadian clock gene expression (*clockb, cry1b, cry2, per1b, arntl1a*) using real-time qPCR. Rhythmicity of gene expression was analysed using Cosinor (Molcan, 2023). Gene expression correlations were assessed using Spearman's correlation matrices in RStudio.

## Results

During embryonic development, expression patterns of clock genes were random with no clear daily rhythm, indicating the circadian clock mechanism had not yet become functional. The Eurasian perch larvae displayed rhythmic expression of circadian genes starting at 3 DPH, coinciding with onset of exogenous feeding, with peaks and troughs in *per1b*, *clockb*, *arnlt1a*, and *cry1b* aligned with transitions between the day and night. The highest expression amplitude was recorded for *cry1b*, while *arnlt1a* had the lowest. Rhythmicity of the analysed genes persisted and became more consistent at the end of the larval period (around 28 DPH).

*(Continued on next page)*

**Discussion**

This study provides the first detailed description of the development of circadian clock gene rhythmicity in Eurasian perch. The delayed onset of rhythmicity in Eurasian perch in comparison with other investigated teleosts (e.g., medaka, zebrafish, and Senegalese sole) may be linked to its slower development. This suggests that circadian clock development could be tied to the specific ecological needs and life history traits of each species. Prolonged embryogenesis of the Eurasian perch which takes place in a relatively safe microenvironment of the chorion, further protected by gelatinous matrix around the eggs might delay the need for a functional circadian clock. Therefore, the Eurasian perch might prioritize the development of other functions, such as visual and motor systems, before activating the circadian mechanism. The rhythmic expression of circadian clock genes began synchronously at 3 DPH. The timing of the onset of circadian clock gene rhythmicity coincides with the beginning of exogenous feeding. The presence of a functional circadian clock at this developmental stage may optimize feeding strategies by synchronizing larval activity with diel zooplankton migrations, thereby enhancing foraging efficiency and reducing predation risk. (Mikheev & Wanzenböck, 2010). As development progressed, these rhythms became more consistent in juveniles, likely reflecting the maturation of the nervous system and improved regulation of circadian processes.

This study not only enhances our understanding of circadian clock development in non-model species but also contributes to the broader knowledge of how circadian rhythms evolve in response to environmental factors. Our data shed light on how early life stages in this species are synchronized with natural light-dark cycles, which is critical for survival, growth, and feeding in the wild. In an ecological context, disruptions to these rhythms - such as through increasing levels of artificial light at night (ALAN) - could interfere with key biological processes, potentially affecting recruitment success and population dynamics. From an aquaculture perspective, the common practice of rearing Eurasian perch larvae under constant light conditions could profoundly alter the natural development of their circadian system, with potential consequences for growth, digestion, behaviour, stress resilience, and long-term welfare.

## Introduction

European strategies in aquaculture are prioritising sustainable feeding practices and the use of functional additives to reduce dependence on antimicrobials. Medicinal plants and plant-derived compounds represent promising alternatives to antibiotics and immunoprophylactics, offering environmental safety and cost-effectiveness compared to synthetic drugs. Among these, *Artemisia annua* has gained attention as a functional feed additive. This fast-growing annual herb contains artemisinin and other bioactive compounds with diverse pharmacological properties, including antibacterial activity and modulation of pathogen-induced immune and metabolic responses (Wang et al., 2023). Artemisinin generates reactive oxygen species that damage parasite cell membranes and disrupt mitochondrial function (Li et al., 2005). Given these bioactivities, dietary *A. annua* may enhance fish health, strengthen disease resistance, and reduce antibiotic reliance in aquaculture. The present study evaluates the effects of a diet supplemented with *A. annua* leaves on oxidative stress markers and plasma biochemical parameters in gilthead sea bream (*Sparus aurata*).

## Material and methods

For the present study, a total of 144 juvenile sea bream (47.18 ± 6.60 g) were randomly distributed into 12 polyethylene tanks (1 $m^3$ each) at the Centro Oceanográfico de Canarias (COC-IEO), CSIC. In each tank, six individuals were randomly selected and tagged with microchips. Four treatments (2 diets x 2 injections) were evaluated, with 3 tanks per treatment. Two dietary treatments were tested: a control group received a commercial diet (control; 6 tanks) and an experimental group that received the same diet plus 30 g/kg of dried *A. annua* powdered leaves (experimental; 6 tanks). Fish were fed daily at 3 - 5% of their biomass, divided into three equal meals. Following 37-days, three fish per tank were intraperitoneally injected with either 5 mg/kg body weight of *Escherichia coli* lipopolysaccharide (LPS; 3 tanks per diet) or an equivalent volume of phosphate-buffered saline (PBS; 3 tanks per diet). Forty-eight hours later, injected fish were euthanised and sampled. Subsequently, the *A. annua* dose in the experimental diet was reduced to 10 g/kg and the same sampling procedure repeated after 62-days. At both times, blood was collected from the caudal vein using heparinised syringes, and gills, liver, intestinal and muscular samples were obtained and stored at −80 °C until biochemical and antioxidant enzyme response analyses were performed.

## Results

At 37 days, glucose levels decreased in LPS-injected fish fed the control diet ($p = 0.033$), while chloride and lactate remained unaffected by diet or LPS. At 62-days, *A. annua* supplementation significantly reduced glucose compared to control dietary and LPS groups ($p = 0.001$ in control, $p = 0.000$ in LPS), but increased lactate ($p = 0.022$ in control, $p = 0.021$ in LPS). At both times, an ionic imbalance was observed: potassium increased ($p = 0.000$ at 37-days and 62-days), while sodium decreased ($p = 0.000$ at 37-days; $p = 0.004$ at 62-days) with *A. annua* supplementation compared with the control diet. *A. annua* also altered antioxidant enzymes and lipid peroxidation. At 37-days, *A. annua* feeding reduced intestinal catalase (CAT) activity after LPS injection ($p = 0.011$). In the liver, superoxide-dismutase (SOD) activity showed variations associated with both diet and LPS treatment, while in muscle, glutation-S-tranferase (GST) activity decreased with *A. annua* supplementation (Table I). Regarding lipid peroxidation, malondialdehyde (MDA) content in the intestine and gills decreased after LPS injection with *A. annua* diet ($p = 0.024$ and $p = 0.046$, respectively). At 62-days, gills-CAT and GST decreased by *A. annua* feeding (CAT: $p = 0.000$; GST: $p = 0.000$). Moreover, GST increased after LPS injection in *A. annua* diet. In muscle, CAT activity varied with diet and LPS injection, while in the liver, *A. annua* reduced SOD and increased MDA in both groups (Table I). In the intestine, MDA content increased with the experimental diet following LPS injection ($p = 0.000$).

D, diet; I, LPS-injection; In, interaction. * Significant differences (Two-way nested ANOVA).

Discussion and conclusions

Despite previous studies have demonstrated the efficacy of *A. annua* supplementation in improving health outcomes, these effects were not observed in the present study. Decreases in glucose levels have also been reported by Eisenman et al. (2011) with *A. draconunlus* supplementation in rainbow trout, likely due to its antidiabetic properties. The observed increase in lactate, indicative of metabolic stress or anaerobiosis, likely results from disrupted ionic homeostasis, suggesting a negative physiological response to *A. annua* supplementation. *A. annua* has been shown to reduce lipid oxidation and regulate lipid metabolism in *Hexagrammos otakii* (Wang et al., 2023) and *Cyprinus carpio.* (Hoseini et al., 2022). Nevertheless, in this study causes clear imbalances in oxidative response enzymes and differences in MDA content. Previous research using *A. arborescens* as a dietary supplement has demonstrated detrimental effects on growth performance, immune response, and blood parameters in sea bream (Tzortzatos et al., 2024), corroborating our present findings. Consequently, supplementation with *A. annua* appears to induce stress in sea bream, highlighting the need for further research on lower dosages to assess its potential benefits.

# EFFECTS OF MS-222 ANAESTHESIA ON OXIDATIVE STRESS IN *Seriola dumerili*

Michelle Barreto-Bailet[1,2*], Salvador Jerez[1], Beatriz C. Felipe[1], M. Jesús Lago[1], M. Virginia Martín[1]

Introduction

*Seriola dumerili* is a high-value species with significant potential for aquaculture diversification, a rapidly growing industry that faces challenges such as developing appropriate procedures and conditions to ensure animal welfare and optimal growth. Anesthesia plays a key role in minimizing handling stress and preventing physiological alterations during experimental or farming procedures. Once absorbed through the gills, anesthetics reach the central nervous system, reducing stress responses by lowering neural activity, metabolism, and oxygen consumption (Zahl et al., 2012). The ideal anaesthetic should act rapidly, allow quick recovery, and avoid disrupting physiological balance. However, most anesthetics can act as stressors, altering respiration, circulation, metabolism, and oxidative status. Elevated levels of reactive oxygen species (ROS) and changes in key antioxidant enzymes, such as catalase (CAT), glutathione S-transferase (GST), and superoxide dismutase (SOD), are indicators of oxidative stress and tissue damage. Tricaine methane-sulfonate (MS-222) is one of the most commonly used anesthetics for poikilotherms worldwide. Its efficacy is influenced by both environmental factors and biological characteristics, including age, sex, size, weight, lipid content, species, and fish density. Consequently, variations among species, developmental stages and social behaviour should be considered when determining the appropriate dosage (Topic Popovic et al., 2012). Due to limited knowledge on the physiological effects of anesthesia in *S. dumerili*, establishing species-specific protocols to monitor and mitigate stress remains a critical challenge. This study aimed to assess the impact of MS-222 on oxidative damage and antioxidant responses in *S. dumerili*, with the objective of identifying potential stress biomarkers for this species.

Material y methods

For this study, a group of 16 captive-born greater amberjack (*Seriola dumerili*) (3.9 ± 1.0 kg; 55.3 ± 5.1 cm) from the Centro Oceanográfico de Canarias (COC-IEO, CSIC; 28°29'56.1"N, 16°11'44.2"W) were anesthetized with MS-222 (tricaine methanesulfonate) at a concentration of 0.1 g/L of seawater, achieving complete loss of reflexes in under 3 minutes. Four groups were established: a control euthanised after initial anaesthesia, and three experimental groups differing in recovery time before a second anaesthesia and sacrifice: 0 h, 1 h, and 24 h. For each group, the times of loss of balance and loss of reflex activity were recorded, followed by the recovery time of the anesthetized fish. After euthanasia, gills, brain, liver and muscle tissues were collected and stored at –80 °C for subsequent analysis of antioxidant enzyme activity.

Results

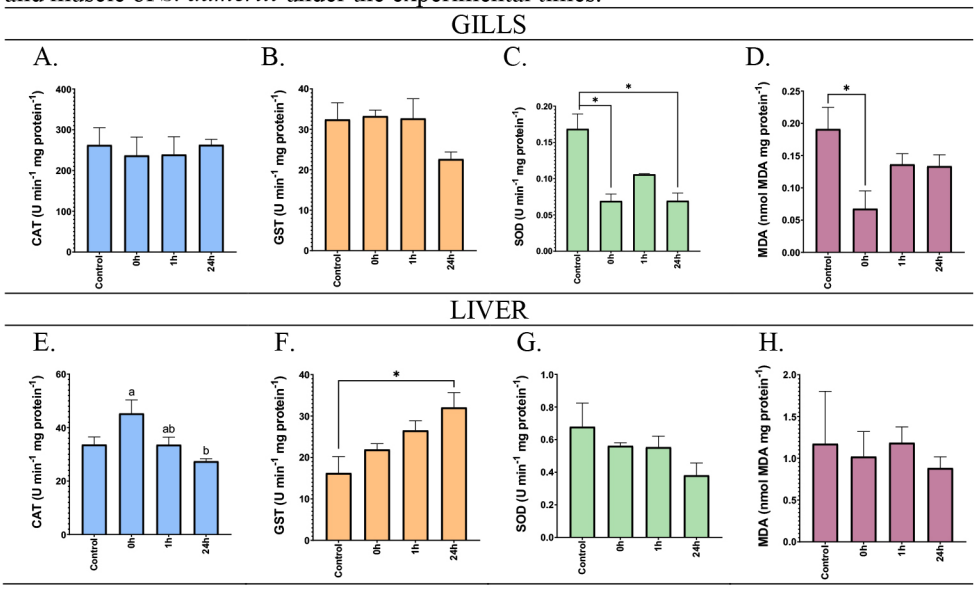
MS222 had pronounced effects on oxidative stress markers across tissues. CAT activity in the brain was significantly lower than the control at all sampling times (0 h: $p = 0.003$; 1 h: $p = 0.001$; 24 h: $p = 0.011$). In the liver, CAT activity was highest at 0 h, but not significantly compared to the control (Fig. 1E). SOD activity showed a significant decrease in the gills compared to the control at both 0 h and 24 h (Fig. 1C). In muscle, SOD activity differed significantly among experimental times, with the highest value at 0 h; however, no significant differences from the control were detected, and either in the liver. GST activity in the liver differed significantly from the control only at 24 h (Fig. 1F). In muscle, GST activity varied significantly among times, with the lowest value at 24 h; however, the only significant difference from the control occurred at 0 h ($p = 0.012$). MDA content in the gills was significantly reduced compared to the control, with the greatest decrease at 0 h (Fig. 1D), whereas no significant differences were detected in the liver (Fig. 1H).

Discussion and conclusions

The sedation and anaesthesia times observed with MS-222 in *S. dumerili* were adequate and comparable to those reported by Maricchiolo and Genovese (2011). However, MS-222-induced oxidative disturbances were found to be tissue-specific. Several studies have shown that MS-222 alters fish physiology and blood parameters (Topic Popovic et al., 2012). Oxidative stress in fish involves increased oxidation products and changes in the activities and concentrations of the components of the endogenous antioxidant system, with oxidative stress being a primary mechanism of tissue damage and physiological disorders. Sustained

*(Continued on next page)*

Fig.1. Catalase (CAT), superoxide-dismutase (SOD), glutation-S-tranferase (GST) (U $min^{-1}$ $mg^{-1}$ protein), and malondialdehyde content (MDA, nmol MDA $mg^{-1}$ protein) in gills and muscle of *S. dumerili* under the experimental times.



inhibition of CAT in the brain and a significant reduction in SOD in the gills indicate a deterioration of antioxidant defences in two critical systems. The gills are the main site of gas and ion exchange, while the brain is the centre of neural regulation; thus, increased reactive oxygen species in these tissues can have serious implications for fish behaviour and physiology. These findings suggest that, while MS-222 provides rapid anaesthesia, it significantly alters the oxidative balance in key organs in *S. dumerili*, making it less suitable for contexts where oxidative homeostasis is critical, especially in studies related to neural or gills physiology.

# PREVENTLICE: A DECISION SUPPORT TOOL FOR SEA LOUSE PREVENTION BASED ON HYDRODYNAMIC AND SITE EXPOSURE DATA

Luke Barrett[1]*, Jon Albretsen[2], Anne Sandvik[2], Tim Dempster[1], Frode Oppedal[3] and Tina Oldham[3]

## Introduction

In regions where salmon lice (*Lepeophtheirus salmonis*) are endemic, Atlantic salmon (*Salmo salar*) farmed in open sea-cages accumulate lice, and eventually must be harvested or deloused to remain under mandated thresholds. This brings substantial animal welfare and economic costs. As most infective lice larvae are found near the surface, new infestations can be prevented or slowed by installing mesh or tarpaulin barriers at relevant depths to keep planktonic louse larvae out of the cage, by encouraging fish to swim deeper through use of deep lights and feed delivery, or by submerging the entire cage to hold fish below the depths that usually contain the most infective larvae. However, each approach has benefits and drawbacks depending on local hydrodynamic conditions and other factors. Within the FHF project PreventLice, we compiled new and existing knowledge on how salinity, temperature, density, currents, and wave exposure affect the efficacy of barriers and deep lighting/feeding methods, and by combining this knowledge with local predictions from a national-scale hydrodynamic model, generated bespoke initial recommendations for every active salmon farm in Norway, available through a free web app and data archive. The app is now being expanded to address the use of submerged cages, develop a universal index of wave exposure, and provide decision support for new sites as part of new FHF projects BetterWel, SafeSubmergence, and LusePraksis.

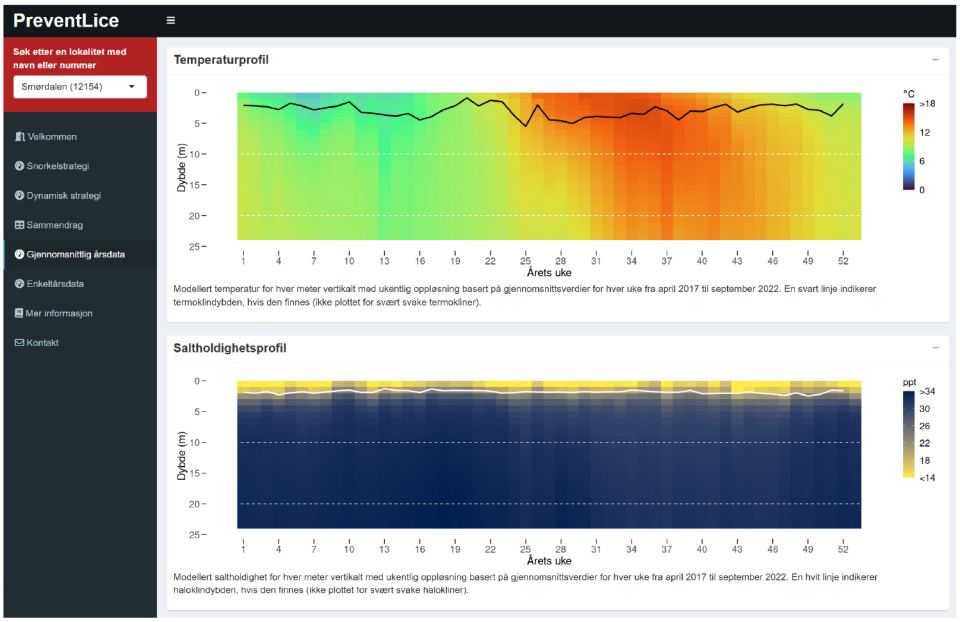

**Figure 1**. Screengrab from the freely accessible PreventLice web app, available in Norwegian at: https://havforskningsinstituttet.shinyapps.io/preventlice/

*(Continued on next page)*

**Methods**

Predictors of successful use of louse barriers were identified by combining existing knowledge (meta-analysis) with new data collection targeted at identified knowledge gaps. This was done through 60 sampling visits at commercial farms distributed along the Norwegian coast throughout all seasons. For over 1000 active salmon farming sites in Norway, we then extracted hydrodynamic and infestation pressure hindcasts from the Regional Ocean Modeling System models NorFjords160 and NorKyst800, and made site-specific recommendations based on the alignment between modelled site conditions and thresholds for efficacy identified through meta-analysis and new data collection. The site-specific hydrodynamic data and recommendations were made available by developing a web app using the *shiny* package for R (Figure 1). We are now processing new data on efficacy of 'skirt' barriers and submerged cages at collaborating sites, which will be used to update recommendations for use of these approaches, especially with respect to site exposure indices.

**Results**

'Snorkel' barriers reduced louse infestations by 80% or more in ideal conditions, when salinity is uniform throughout the water column, but efficacy was significantly reduced when conditions deviate from ideal. Even in ideal conditions, snorkel cages reduced growth compared to controls and lead to increased amoebic gill disease risk, and are increasingly unpopular due to these and other challenges. In contrast, dynamically deployed 'skirt' barriers in combination with behavior modification reduced infestations by >50% compared to standard production cages, regardless of temperature and salinity variability and without negatively impacting growth, gill health, or other welfare metrics. Efficacy of both approaches was reduced at sites with exposure to large waves, but not strongly impacted by surface current speeds of up to 0.8 m $s^{-1}$. Further results will be available by the time of the conference.

# TOWARDS ON-SITE DIAGNOSTICS: A LAMP-BASED APPROACH FOR THE RAPID DETECTION OF *Vibrio harveyi* IN AQUACULTURE

J. Barriga-Cuartero[1*], A. Ghani[2], C. Amaro[1], B. Fouz[1]

[1]University Institute for Biotechnology and Biomedicine Reasearch (BIOTECMED), University of Valencia, Burjassot (Valencia), Spain

E-mail: belen.fouz@uv.es

## Introduction

*Vibrio harveyi* (*Vh*) is a Gram-negative halophilic bacterium found in marine environments worldwide that can cause disease (vibriosis) in numerous aquatic animals, including cultured species. Nowadays, epizootics and outbreaks caused by *Vh* are increasing due to its wider distribution because of global warming (Amaro et al*.,* 2020). Early and accurate diagnosis is crucial for *Vh*-vibriosis management, but traditional methods do not cover these requirements. PCR-based approaches offer improved specificity, but they usually require expensive specialized equipment. However, loop-mediated isothermal amplification (LAMP) presents an insightful alternative that allows for a rapid and highly specific DNA amplification i*n situ* at isothermal temperatures, making it suitable for field deployment. Previous studies on LAMP assays for *Vh* have focused on the *toxR* and *dnaJ* genes, but they have shown limitations (Rahman et al., 2022). In contrast, the *vhhP2* gene, encoding a putative outer membrane protein, has emerged as a promising, highly conserved target across the species. The present study describes the development of a new LAMP assay, targeting the *vhhP2* gene, for *Vh* detection in aquaculture settings.

## Materials and methods

Bacterial strains: a collection of *Vh* strains, representatives of the dominant serotypes (Amaro et al. 2020), was used. Clinical and environmentally relevant *Vibrio* species were also included: *V. vulnificus, V. cholerae, V. parahaemolyticus, V. alginolyticus, V. rotiferianus, V. campbellii* and *V. anguillarum*. Strains were grown on Tryticasein Soy Agar or Luria-Bertani broth supplemented with 1 % NaCl (TSA-1 or LB-1) at 28 ºC.

DNA extraction: genomic DNA from bacterial strains was extracted using a modified boiling method. After a final centrifugation, the supernatant containing the extracted DNA was collected and stored at -20 ºC for subsequent use.

**Table 1.** Set of LAMP primers targeting the *vhhP2* gene of *Vibrio harveyi.*

| LAMP primer | Size (bp) | Sequence (5'-3') |
|---|---|---|
| vhhP2_F3 | 24 | TTACCCTACTAGAACTTATCATTG |
| vhhP2_B3 | 19 | TTCCTGTGTTCCACCATTG |
| vhhP2_FIP | 38 | ACGCATCGTCTTGGAGGTTTATTCTCGGCATCCTAGCT |
| vhhP2_BIP | 43 | TCAAGCAAAAATGGAATCCATCGCATTGGCTTTGGGTAAATCG |

| vhhP2_LB | 20 | TGACCAATTCGAAACAGGCG |

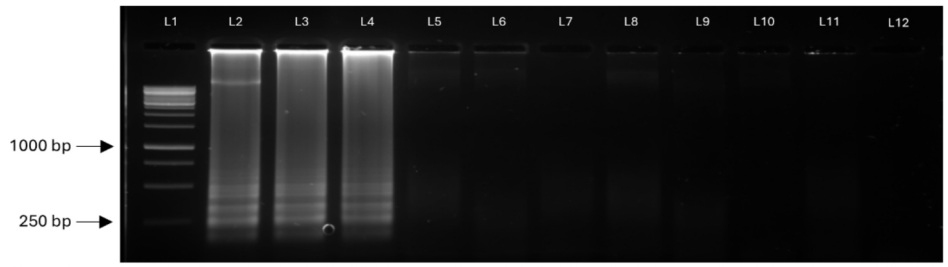

**Figure 1. Gel electrophoresis of the LAMP assay**. Lane (L) 1: 1 kb DNA ladder; L2: *Vibrio harveyi* (*Vh*) C2; L3: *Vh* C3; L4: *Vh* 203; L5: *V. vulnificus* CECT 4999; L6: *V. cholerae* B4; L7: *V. alginolyticus* Lub 1; L8: *V. anguillarum* Lab1; L9: *V. parahaemolyticus* TW2; L10: *V. campbellii* NCIMB 1894$^{T}$; L11: *V. rotiferianus* CAIM 577$^{T}$; L12: negative control (distilled water).

*(Continued on next page)*

Primer design: a set of six LAMP primers, comprising two inner (FIP/BIP), two outer (F3/B3), and two loop (LF/LB) primers, were specifically designed to target the conserved *vhhP2* gene region of *Vh* using GLAPD software (Jia et al., 2019). To ensure specificity and prevent non-specific hybridization, all primer sequences were rigorously verified *in silico* using Primer-BLAST tool. The final selected primers were synthesized by Integrated DNA Technologies (IDT, Belgium).

LAMP amplifications: LAMP reactions were performed in a total volume of 25 µL. Each reaction mixture contained: 1.6 µM each of FIP and BIP, 0.2 µM each of F3 and B3, 0.4 µM each of LF and LB, 1.4 mM each deoxynucleoside triphosphate (dNTPs), 8 mM $MgSO_4$, 1 µL of target DNA and 8 U of Bst 2.0 WarmStart ® DNA Polymerase (New England Biolabs). Amplifications were carried out at a constant temperature of 65 °C for 15 min, followed by enzyme inactivation at 80 °C for 10 min. Specificity was evaluated using DNA templates from the selected *Vibrio* species. Sensitivity was assessed by testing 10-fold serial dilutions of *Vh* genomic DNA. LAMP products were subsequently analyzed by 1.8 % agarose gel electrophoresis for visualization.

**Results and Discussion**

The developed LAMP assay, targeting the *vhhp2* gene with a comprehensive set of six primers (**Table 1**), demonstrated excellent results for *V. harveyi* detection.

Specificity assessment. All *Vh* strains tested in the study yielded a positive amplification signal. Crucially, the assay exhibited no cross-reactivity with any of the *Vibrio* species tested (**Figure 1**). Its high specificity is a powerful advantage, particularly in complex aquatic environments where multiple *Vibrio* species coexist, as occurs in aquaculture settings.

Sensitivity evaluation. The LAMP assay achieved a limit of detection (LOD) of 100 fg/µL of *Vh* genomic DNA. Its sensitivity was higher than most conventional PCR-based methods, even within a rapid 15-minute amplification period. Thus, the potential of this technique for early *Vh* detection is highlighted, even in the initial stages of infection or in environmental samples where bacterial load might be minimal.

**Conclusions**

We have developed a novel LAMP assay for *V. harveyi* detection, targeting the conserved *vhhP2* gene, highly sensitive and specific.

This rapid, isothermal diagnostic tool offers a cost-effective and practical solution for on-site application in aquaculture.

**Introduction**
Senegalese sole (*Solea senegalensis*) is a species of high commercial value in southern Europe, particularly in Portugal and Spain. The development of microdiets for flatfish larvae is essential to optimize hatchery protocols and augment juvenile quality. During early developmental stages, marine fish larvae have a limited ability to digest and absorb complex proteins (Engrola et al., 2009; Gamboa-Delgado et al., 2008). Therefore, including protein hydrolysates in larval feed formulations known to enhance protein absorption and growth in several marine fish species may be a viable nutritional strategy to overcome this biological constraint (Canada et al., 2017; Delcroix et al., 2015; Srichanun et al., 2014). Protein hydrolysates present a high bioactive potential for marine larval production, particularly by modulating antioxidant defences, enhancing immune responses, and improving digestive function. Their bioactive peptides can help maintain redox balance, support mucosal immunity, and stimulate enzyme activity, contributing to healthier and more resilient animals (Canada et al., 2017; Delcroix et al., 2015). The aim of the present study was to investigate the potential of incorporating protein hydrolysates in microdiets to improve larval quality in Senegalese sole, focusing on growth and resilience.

**Materials and Methods**
The trial was conducted at CCMAR's experimental facilities. Larval rearing took place in 100L tanks in RAS under optimal abiotic conditions for the species. Larvae were co-fed with microdiets and live-prey from mouth opening (2 days after hatching – DAH) until the end of the trial at 18 DAH. Two microdiets were tested in triplicate tanks: diet Low (commercial-like diet with low molecular weight protein hydrolysates) and diet High (commercial-like diet with high molecular weight protein hydrolysates). For the assessment of performance, larvae were sampled at 2, 12, 16 and 18 DAH for weight and length. Survival was determined at 18 DAH. A 24 h thermal challenge was conducted from 16 to 17 DAH, where the temperature of the water was increased 5ºC compared to standard conditions, to evaluate the larvae resilience. At 16 and 17 DAH, physiological biomarkers of oxidative stress (catalase, superoxide dismutase, total antioxidant status and lipid peroxidation) were assessed. Additionally, the expression levels of genes related to digestion (*pept1*, *ialp*, *tryp*), antioxidant defence (*sod*, *cat*, *gpx4*, *nrf2*), and cellular stress (*hsp60*, *hsp70*) were evaluated.

**Results and Discussion**
Biometric data (weight, length and condition factor) showed significantly improved larval performance up to 12 DAH in the High treatment. At 16 DAH, the Low larvae showed better performance indicators. It is known that the digestive capacity of sole decreases during the climax of metamorphosis (Canada et al., 2017; Engrola et al., 2009). The observed shift in performance relative to peptide size suggests that larvae between 12 and 16 DAH benefited from a diet containing lower molecular weight peptides during this transitional phase.

Oxidativestress biomarkers did not vary significantly across groups or sampling points, regardless of diet or thermal challenge. No significant differences in gene expression levels were observed at 16 DAH. However, sole fed the Low diet showed a significant upregulation of *cat, nrf2, pept1* and *hsp60* following the thermal challenge at 17 DAH. This transcriptional response suggests that low molecular weight hydrolysates may enhance cellular readiness to cope with oxidative and thermal stress by supporting antioxidant defence (*cat*, *nrf2*), nutrient uptake (*pept1*), and protein homeostasis (*hsp60*).

These results highlight the potential of tailored diets to improve growth of Senegalese sole during the metamorphosis, as well as enhancing stress resilience during early developmental stages in marine fish larvae.

## Introduction

In fishes, axial musculature accounts for 60–70 % of body weight and is largely composed of white muscle fibres, which are of high commercial interest. Unlike in mammals, these fibres are generated during myogenesis, a process that can form new muscle fibres even after sexual maturity in several teleosts, such as E. sea bass. This myogenic process is driven by satellite cells, which play a crucial role in continued muscle growth; they proliferate, differentiate, and fuse into myotubes through the action of myogenic regulatory factors (MRFs) such as myod, myf5, myogenin, and mrf4. Growth is also regulated by the GH/IGF axis, in which growth hormone (GH), secreted by the pituitary, stimulates the liver to produce insulin-like growth factors (IGFs), which act in target tissues to stimulate growth via the PI3K–Akt–mTOR and MAPK pathways. The IGF system comprises IGF-1 and IGF-2, their receptors (IGF-1ra, IGF-1rb), and binding proteins (IGFBPs). Therefore, this study aims to determine the effects of IGF-1 and IGF-2 under optimal proliferation conditions, analyse the expression of key markers at the proliferation (day 5) and differentiation (day 8) stages, and evaluate differences in the proliferative effects of IGF-1 and IGF-2 on E. sea bass myogenic cultures.

## Material and methods

E. sea bass fingerlings (10 ± 3 g; Culmarex, Murcia, Spain) were used to establish primary myocyte satellite cell cultures from epaxial muscle. Cells were seeded at $7.5 \times 10^5$ cells/mL in 6 well plates coated with poly-L-lysine followed with laminin and maintained at 23 °C and 2.5 % $CO_2$. Seven independent cultures were used for 5-bromo-2□-deoxy-uridine (BrdU) proliferation assays in 96 well plates, each condition in triplicate. After 12 h of fetal bovine serum (FBS) starvation, cells (day 4) were treated with IGF-1 from chicken (CH1; 100, 500 ng/mL), IGF-1 from sea bream (SB1; 100, 500 ng/mL), or IGF-2 from chicken (CH2; 100, 500 ng/mL), plus controls with and without FBS (10 % or 0 %). BrdU (10 $\mu$M) was added after 5 h, and cells were fixed 5 h later; the immunofluorescence detection was performed according to the manufacturer's protocol (11 296 736 001; Roche, Basel, Switzerland). The most proliferative dose for each IGF was then tested in 6 well plates to assess growth-related gene expression at days 5 and 8 (controls, CH1 and SB1 at 100 ng/mL, CH2 at 500 ng/mL), following 12 h of FBS starvation and 24 h of treatment.

## Results and discussion

BrdU assays revealed an increased proportion of labelled nuclei in treated cells with 100 ng/mL IGF-1 (CH1 and SB1), while the same statistical significance required a concentration of 500 ng/mL in IGF-2 treated cells (Figure 1). This may indicate that lower levels of IGF-1 are sufficient to promote proliferation. Additionally, *igf-1* transcript levels were low at both day 5, and 8, in contrast to *igf-2*, which showed higher expression, suggesting a predominantly proliferative role for IGF-1 and a differentiation-oriented role for IGF-2, in contrast to what has been reported for sea bream Azizi et al., 2016).

During peak proliferation (day 5), cells treated with IGFs showed a slight increase in *pcna* expression, possibly reflecting enhanced cell proliferation activity. In contrast, *myod1* expression was significantly downregulated in all IGF treatments, whereas *myod2* expression was higher, which may indicate that IGF treatment accelerated the myogenic programme and promoted more proliferation. On the same day, *igfbp-3a* and *igfbp-5b* were also upregulated in CH1 and CH2, suggesting a possible regulation mechanism aimed at modulating IGF bioavailability. No significant differences were observed for the

*(Continued on next page)*

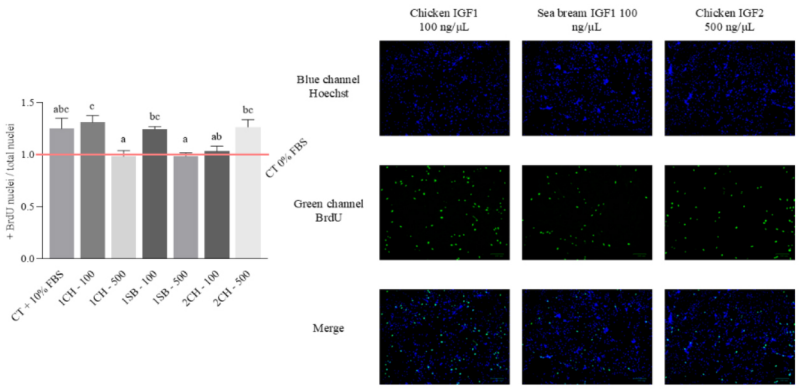

**Figure 1:** BrdU-positive nuclei relative to total nuclei stained with Hoechst in E. sea bass myocyte cultures treated with the selected doses of IGF-1 from chicken (CH1, 100 ng/mL), IGF-1 from sea bream (SB1, 100 ng/mL), and IGF-2 from chicken (CH2, 500 ng/mL). Representative images show Hoechst staining (blue channel), BrdU labelling (green channel), and merged images.

remaining genes at this stage. As cultures progressed to the differentiation phase (day 8), *myod1* expression decreased further compared to day 5, while myod2 showed significant upregulation in all IGF treatments, consistent with increased myoblast differentiation. *Myogenin* expression was slightly higher in IGF-1 and IGF-2 from chicken, while *mrf4* expression and *myhcb* increased overall compared to day 5, likely reflecting progression from proliferation towards late-stage differentiation and maturation of myotubes.

Overall, the results indicate that both IGF-1 and IGF-2 stimulate proliferation and differentiation of E. sea bass white muscle satellite cells, promoting an earlier transition from proliferation to differentiation and involving feedback regulation of IGF bioavailability. At this stage, eif4ebp1 expression in the IGF-1 (chicken) treatment tended to be higher, possibly indicating a role for IGF-1 in promoting differentiation. Core signalling and fusion-related genes remained unaffected, and both IGFs displayed proliferative effects, although IGF-2 required a higher concentration to match IGF-1 responses, supporting their potential use to enhance muscle growth efficiency in E. sea bass myocytes primary culture.

**Introduction**

Successful aquaculture relies on healthy broodstock, which ensures high-quality gametes. Nutrition plays a critical role in reproductive performance and has recently shifted toward more sustainable protein sources (Migaud et al., 2013). Fishmeal is increasingly being replaced by alternatives such as insect meals. While insect meal has been widely studied for growth and meat quality (Alfiko et al., 2022), little is known about its effects on broodstock reproductive traits and gamete quality. Limited studies in species like zebrafish and brown trout have shown mixed results (Chemello et al., 2022). Thus, the long-term reproductive effects of insect-based feeds remain largely unknown.

**Materials and methods**

Freshly hatched African catfish (*Clarias gariepinus*) larvae were fed Artemia nauplii for the first five days post-hatch. Following this initial period, experimental diets were introduced. The Control group received only commercial feeds, while in the BSF33 group, 33% of the feed was replaced with Black Soldier Fly (*Hermetia illucens*) (BSF) meal, and in the BSF50 group, 50% of the feed was substituted with BSF meal. Fish were maintained in a continuous recirculating aquaculture system (RAS) at a constant temperature of 25 ± 1 °C.

To ensure optimal broodstock selection, continuous growth measurements and phenotypic selection were carried out throughout the rearing period. After 18 months of culture, 5 males and 5 females from each group were selected and used for propagation. Individual body weight and stripped egg quantity were recorded. Additionally, the weight of the testes and liver was measured for each individual.

The number of eggs per gram was also determined by manually counting the eggs in a 1-gram subsample of stripped eggs. Based on these measurements, the gonadosomatic index (GSI) was calculated as gonad weight / body weight × 100, and the hepatosomatic index (HSI) as liver weight / body weight × 100.

**Results**

No significant differences were observed among the dietary groups in terms of body weight, egg size, gonadosomatic index (GSI) in either sex, or hepatosomatic index (HSI). All measured parameters remained statistically similar across the Control, BSF33, and BSF50 groups (Table 1.).

**Discussion**

In our experiment, 33% and 50% of the commercial feed was replaced with black soldier fly larvae (BSFL) meal. We examined the effects of the different diets on egg diameter, the gonadosomatic index (GSI), and the hepatosomatic index (HSI). Even at the highest level of BSFL inclusion, no statistically significant differences were observed. The values obtained for egg size (Hogendoorn, 1980; Opiyo et al, 2017), GSI (Mikaheel et al., 2019), and HSI (Ajang et al., 2018) were consistent with those reported in the literature.

**Conclusion**

Replacing 33% and 50% of the complete feed with black soldier fly larvae meal has no negative effect on egg size, GSI, or HSI.

**Introduction**

Endocrine-disrupting chemicals (EDCs), particularly estrogenic xenoestrogens, are prevalent environmental pollutants that accumulate in surface waters, posing serious ecological and health risks. These compounds can cause feminization, altered sex ratios, reduced fertility in wildlife, and reproductive, immunological, cardiovascular, and oncogenic effects in humans. Due to their chemical diversity, EDCs require varied analytical approaches, and their estrogenic activity cannot always be predicted from structure alone. In nature, they usually occur as complex mixtures whose biological effects are influenced by concentration, solubility, degradation rate, microbial transformation, and environmental conditions. These factors complicate purely chemical detection methods, making bioassays with biomarker organisms a valuable alternative.

Fish are especially suitable vertebrate models for environmental risk assessment. They absorb contaminants across their entire body surface, have short generation times, high fecundity, and share key endocrine pathways with other vertebrates, including humans. Several estrogen-responsive genes have been characterized in fish and used to develop transgenic *in vivo* biosensors, such as zebrafish *(Danio rerio)* reporter lines. Since xenoestrogens affect multiple biological pathways, reliable assessment often requires combined *in vitro* and *in vivo* approaches, which can be time- and resource-intensive and may conflict with the 3R principle. Multicolor transgenic reporter systems, such as multicolor zebrafish lines, offer a promising alternative but remain scarce.

This study aimed to develop a novel multicolor transgenic zebrafish line (Tg(vtg1:mCherry) × Tg(cyp19a1b:GFP)) enabling simultaneous *in vivo* monitoring of vitellogenin- and aromatase-pathway activation. We adapted the EASZY protocol for aromatase analysis to the characteristics of this new line and designed experimental procedures to measure transgene expression in parallel. We tested the estrogenic activity of 17β-estradiol (E2), the fungicide prochloraz, and an water/aqueous extract of Hytrel plastic using transgenic embryos.

**Materials and Methods**

The new biomarker line was created by crossing Tg(cyp19a1b:GFP) and Tg(vtg1:mCherry) zebrafish, selecting F1 individuals carrying both transgenes after 50 µg/L E2 induction. Positive embryos were raised, in-crossed to produce the F2 generation, and characterized by documenting fluorescence development from 1–5 days post-fertilization (dpf) under brightfield, GFP, and mCherry filters. Images were analyzed using ImageJ to calculate integrated density (ID) and GFP fold-change values.

For short-term exposure assays, embryos at the 8-cell stage were treated with E2 (1–200 µg/L), prochloraz (17.5–300 µg/L), or Hytrel extract (4.8 mg/L) until 5 dpf. Imaging conditions (orientation, magnification, and timing) were optimized for each reporter: lateral views for liver-localized mCherry (vtg1:mCherry expression) and dorsal views for brain-localized GFP (cyp19a1b:GFP expression).

*(Continued on next page)*

**Results and Conclusions**

The developmental atlas showed mCherry expression in the liver from day 4, peaking at day 5, and GFP expression in the brain from day 3. Optimal simultaneous detection of both reporters was achieved at 5 dpf, slightly modifying the EASZY protocol's 4-day exposure. Reporter signals were orientation-dependent: lateral imaging best captured liver fluorescence, while dorsal imaging was superior for brain signals.

Prochloraz reduced cyp19a1b expression, indicating anti-estrogenic activity, while Hytrel also suppressed aromatase expression, possibly due to toxicity. Both reporters displayed similar estrogen-sensitivity patterns. The differences in imaging requirements for examining embryos containing the two transgenes support the continued use of dual-orientation imaging in future studies.

**Summary**

We established a multicolor transgenic zebrafish line that combines vitellogenin- and aromatase-based estrogen reporters, enabling rapid and reliable detection of estrogenic or anti-estrogenic activity in a single assay. This system reduces the number of experimental animals required, increases efficiency, and can be applied to diverse chemicals, mixtures, and environmental samples, contributing to improved environmental risk assessment and endocrine toxicology.

## Introduction

Significant amounts of fish and seafood are wasted worldwide due to spoilage and degradation at various stages of the cold chain (EUMOFA, 2022). The development of innovative smart packaging solutions for monitoring the deterioration of fish products could provide consumers with reliable indicators of product freshness, thereby contributing to reduction in food waste (Tsironi et al., 2018; Li et al., 2022). This study focused on the design of freshness indicators responsible for volatile ammonia compounds, facilitating the monitoring of spoilage within fish packaging environments through visible color changes. The smart packaging systems were formulated using starch and polyvinyl alcohol, enriched with anthocyanins derived from pomegranate juice. The objective was to develop biodegradable, environmentally friendly packaging that delivers real-time visual information on the quality and deterioration of packaged fresh fish.

## Materials and methods

The smart packaging system was prepared according to the solvent casting method, incorporating starch and polyvinyl alcohol (PVA) with pomegranate juice added as a natural source of anthocyanidins (Alizadeh-Sani et al., 2020). Aiming at a sustainable production process for the smart indicators, the anthocyanidins from the pomegranate juice were not isolated to eliminate the need for organic solvents and energy-intensive processes. Following preparation, the smart films were characterised for their optical properties, microstructure (SEM), infrared spectrum (FTIR), wettability, water solubility, moisture adsorption (sorption isotherms), color response at various pH values and reactivity to volatile amines commonly produced during fish spoilage, such as ammonia, trimethylamine and dimethylamine. The smart indicators were subsequently placed inside packages containing gilthead seabream (*Sparus aurata*) fillets. The samples were stored under controlled temperature conditions (4°C) for shelf life evaluation based on chemical (pH, TVB-N) and microbiological fish quality indicators (total viable counts, *Pseudomonas* spp. and Enterobacteriaceae). The color change of the indicators (ΔE value) and the gas composition in the package headspace were continuously monitored during the storage experiment.

## Results and Discussion

Scanning electron microscopy revealed satisfactory microstructural integrity and compatibility between the incorporated dye and the biopolymer carrier. Successful incorporation of the dye was further confirmed through Fourier transform infrared spectroscopy. The developed films exhibited suitable optical and mechanical properties for potential packaging applications. The incorporation of pomegranate juice enhanced the hydrophilicity of the membranes (contact angle reduction from 93° to 82°). The color sensitivity test demonstrated that the color response of smart films successfully monitored the increase in volatile amine concentration and pH values, exhibiting a visible color shift from bright red to purple-green. Preliminary results of the application of the freshness indicators within the headspace of packaged gilthead seabream fillets demonstrated their capability to monitor the accumulation of volatile amines and the progression of fish spoilage during refrigerated storage. A perceptible color change (ΔE>3) was observed from the early stages of spoilage (day 4-5), with intensity increasing as degradation advanced. The indicators showed a reliable correlation with changes in headspace gas composition and were consistent with microbiological and chemical quality indicators of fish flesh, highlighting their potential as effective tools for real-time spoilage monitoring.

**Introduction**

Black soldier fly (BSFLO), a by-product of insect meal processing, is characterized by presenting high levels of lauric acid (30-40%), a fatty acid suggested to enhance hepato-metabolic status. Additionally, when sourced from larvae-fed vegetable wastes rich in tocopherols, BSFLO also presents significant levels of these antioxidant compounds. Stress in aquaculture fish, often triggered by factors such as overcrowding, poor water quality, or sudden environmental changes, can significantly impair their immune function, growth rates, and overall welfare. This underscores the critical need for feeding strategies that not only meet the nutritional requirements but also help mitigate stress. Therefore, this study aims to appraise the impact of BSFLO dietary inclusion on the metabolic and oxidative response of European seabass (*Dicentrarchus labrax*) juveniles – a key species in Mediterranean aquaculture – following an acute stress challenge.

**Material and methods**

A control diet (CTRL) was formulated with 6% fish oil and 5% poultry oil (PO). Three other experimental diets were formulated to include 1.7%, 3.4% and 5.2% of BSFLO, supplied by Entrogreen® - Ingredient Odissey S.A. (BSFLO1.7, BSFLO3.4 and BSFLO5.2, respectively), at the expense of PO. Each diet was assigned to triplicate homogeneous groups of 50 fish (11 ± 0.1 g) that were fed until apparent satiation three times daily for 12 weeks. Fish were subjected to a 12-hour light/12-hour dark photoperiod regime and kept in a recirculating saltwater system (35‰, 23 ± 1 °C). By the end of the trial, 5 fish per tank (15 per dietary treatment) were sampled for analysis of metabolic and oxidative stress response-related parameters, and other 5 fish per tank were exposed to an acute stress episode consisting of 1 min air exposure and 14 min overcrowding (100 kg/m$^3$) followed by 90 min of recovery before sampling. Plasma cortisol levels, along with plasmatic and hepatic metabolites (e.g., glucose, lactate, triglycerides, among others) were quantified. Additionally, lipid peroxidation and the activity of oxidative stress-related enzymes (e.g., superoxide dismutase, catalase, and glutathione peroxidase, and others) were measured. Growth performance and feed efficiency were also evaluated.

**Results**

The experimental diets ensured a 100% survival rate, and no behavioural alterations were observed in the fish throughout the 12-week feeding trial. Fish fed the BSFLO5.2 diet achieved the highest final body weight and the lowest feed conversion ratio (FCR). A clear response to acute stress was observed, as indicated by significantly increased levels of plasmatic cortisol, glucose and lactate, as well as lipid peroxidation products in the liver of fish sampled after the acute stress challenge. Based on the Mahalanobis distance between group centroids, fish fed BSFLO5.2 diet were clustered at a significant distance from the other groups either before or after stress challenge (Fisher's $p$-value < 0.0001), with this separation being particularly prominent between the BSFLO5.2 and CTRL groups (Figure 1). Indeed, based on the two-way ANOVA, fish fed BSFLO5.2, specifically after the stress challenge, exhibited significantly lower (Tukey's $p$-value < 0.05) plasma cortisol (Figure 2-A) and cholesterol levels than those fed CTRL. Additionally, BSFLO5.2 group also had significantly lower lipid peroxidation (LPO) (Figure 2-B) and superoxide dismutase (SOD) activity compared to CTRL. Glutathione peroxidase (GPx) activity was also the lowest in seabass fed BSFLO5.2, regardless of stress condition. Although without statistically significance, stressed fish fed BSFLO5.2 also have lower levels of plasma glucose, lactate, and triglycerides, as well as hepatic cholesterol, non-esterified fatty acids (NEFA), and catalase (CAT) activity compared to CTRL-fed fish.

*(Continued on next page)*

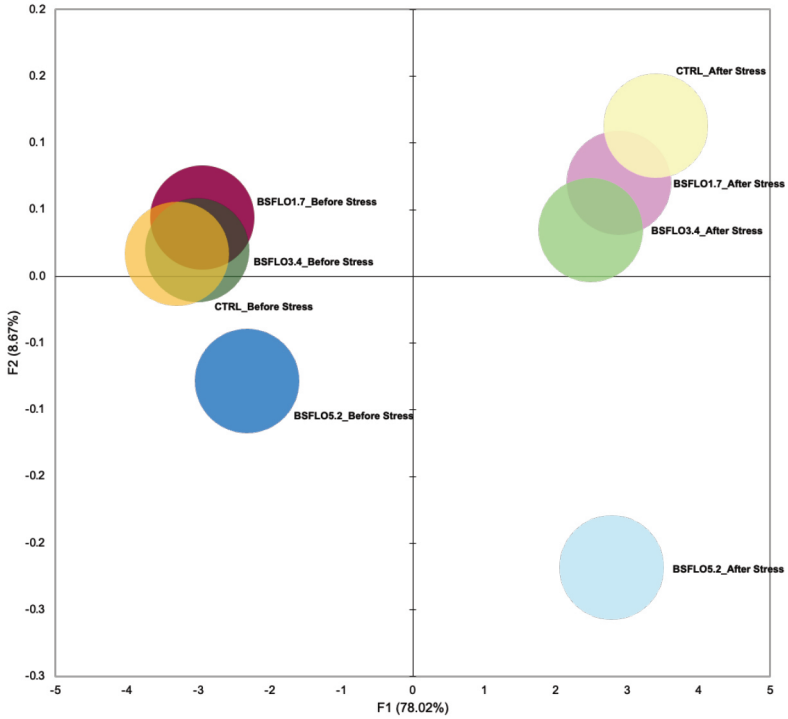

**Figure 1.** Canonical discriminant analysis of European seabass fed experimental diets, before and after stress.

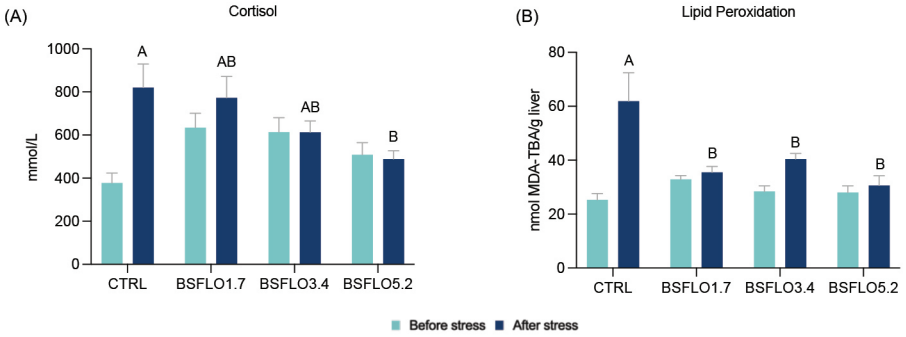

**Figure 2.** Plasma cortisol levels (A) and hepatic lipid peroxidation (B) in European seabass fed experimental diets, before and after stress.

## Discussion and conclusions

European seabass juveniles fed the BSFLO5.2 diet exhibited a marked reduction in cortisol levels - the primary indicator of stress - as well as decreased plasma cholesterol, its metabolic precursor. This attenuation of the stress response can be associated with reduced activation of key antioxidant enzymes, including SOD and GPx, and lower levels of LPO, suggesting diminished oxidative stress. In addition to these physiological benefits, the 5.2% inclusion of BSFLO significantly enhanced growth performance and feed efficiency. Together, these findings indicate that BSFLO, particularly when included at 5.2%, can modulate stress-related pathways while supporting optimal growth in European seabass juveniles, highlighting its potential as a functional ingredient in aquafeeds.

## Introduction

In recent decades, microalgae have gained recognition as high-value biological resources due to their ability to produce a wide array of bioactive compounds with diverse applications in aquaculture, pharmaceuticals, cosmetics, agriculture, food, and feed[1]. This biotechnological potential has driven continuous efforts to enhance microalgal biomass productivity and metabolite accumulation through both cultivation optimization (e.g., light, temperature, nutrients, CO□) and genetic approaches such as metabolic engineering and selective breeding[2-3]. In parallel, random mutagenesis has emerged as a well-established, low-cost and relatively straightforward strategy to generate novel microalgal strains with improved phenotypes, without requiring prior genomic knowledge[4]. Moreover, it enables the selection of mutants even when underlying metabolic pathways are poorly understood. As non-transgenic variants, random mutagenesis-derived mutants face no regulatory restrictions for large-scale application in opposition to genetically modified organisms[4]. These advantages make it a valuable tool to create strains with desirable attributes, such as accelerated growth or high biometabolite output, suitable for industrial cultivation. Among microalgae, the marine diatom *Phaeodactylum tricornutum* stands out for its fast growth, ease of cultivation, and ability to synthesize high-value compounds such as fucoxanthin and omega-3 fatty acids[5]. It is widely used as a nutritious feed in aquaculture, providing a high protein content (≈ 49% of biomass) and accumulating up to ≈ 35% EPA, which is essential for fish larvae and molluscs[6]. Beyond aquaculture, *P. tricornutum* is also considered a promising production platform for market-relevant bioproducts in the pharmaceutical and nutraceutical sectors[5]. Nevertheless, maximizing *P. tricornutum* productivity under large-scale cultivation remains a challenge, underscoring the importance of strain improvement and process optimization to enhance economic feasibility and competitiveness. In this context, the present study aimed to assess the growth performance and biomass productivity of a *P. tricornutum* mutant strain (MT009), obtained through random mutagenesis, in comparison with the wild-type (WT) strain when cultivated in pilot scale flat-panel photobioreactors.

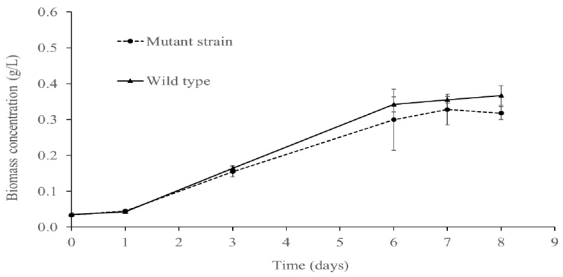

**Figure 1**: Biomass concentration (g $L^{-1}$ DW) of MT009 and wild-type *P. tricornutum* strains over 8 days of outdoor cultivation in 100 L flat-panel photobioreactors (mean ± SD, $n = 3$).

*(Continued on next page)*

**Material and Methods**

The *P. tricornutum* mutant strain (MT009) was generated through chemical mutagenesis using ethyl methanesulfonate (EMS) at a final concentration of 200 mM for 60 minutes under constant agitation. In a previous screening assay, MT009 and WT strains were cultivated under different salinities (5, 20 and 35 ppt) and temperature conditions to select the best cultivation conditions. Cultivation at 33 ppt of salinity and 28ºC was selected. The MT009 and WT *P. tricornutum* strains were subsequently scaled up from 250 mL to 1 and 5 L round-bottom flasks under controlled temperature, and then cultivated for 8 days in 100 L outdoor flat-panel photobioreactors (FP-PBRs) operated in fed-batch mode. Finally, each culture was split into three 100 L FP-PBRs ($n$ = 3). All FP-PBRs cultures were exposed to natural light and ambient temperature (average temperature of approximately 18ºC), with continuous mixing provided by bubbling aeration. The pH was maintained around 8.2 through periodic $CO_2$ injection. The culture medium consisted of UV-sterilized, ultrafiltered natural seawater enriched with NutriBloom® Plus. Growth and nitrate uptake were monitored daily by measuring optical density (OD) at 540 and 220/275 nm, respectively. Biomass concentration (dry weight, DW), was estimated using $OD_{540}$-to-DW calibration curves. Biomass productivity (g $L^{-1}$ $day^{-1}$) was calculated from DW and cultivation time, and the specific growth rate (μ) was determined during the exponential phase using: $\mu = [\ln(N_2) - \ln(N_1)]/[t_2 - t_1]$, where $N_1$ and $N_2$ are biomass concentrations at times $t_1$ and $t_2$, respectively.

**Results and Discussion**

Both strains were scale-up in 100 L FP-PBRs to ensure equivalent inoculation conditions, sufficient biomass, and physiological acclimation to the cultivation system. At the end of this scale-up, the MT009 and WT strains had reached 0.28 and 0.21 $gL^{-1}$ DW, respectively. The cultures were then split into three 100 L FP-PBRs to initiate a 8-day comparative trial. Both cultures displayed steady exponential growth from day 1 to 6 (Fig. 1), culminating in final biomass concentrations of 0.32 ± 0.02 $gL^{-1}$ for the mutant and 0.37 ± 0.03 $gL^{-1}$ for the WT. The WT exhibited a slightly higher specific growth rate (μ = 0.414 $day^{-1}$) than the mutant (μ = 0.377 $day^{-1}$), suggesting a marginal advantage in growth kinetics under the tested conditions. Although modest, this difference may reflect subtle variations in cellular metabolism, light-use efficiency, or nutrient assimilation. Nonetheless, the mutant followed a similar growth trajectory, reaching a peak biomass productivity of 0.0546 g $L^{-1}$ $day^{-1}$ on day 3 compared to 0.0606 g $L^{-1}$ $day^{-1}$ for the WT. WT reached stationary phase on day 6, and MT009 strain on day 7 as indicated by biomass stabilization and productivity decline, likely due to nutrient depletion, self-shading, or metabolite accumulation.

In conclusion, the *P. tricornutum* MT009 strain exhibited growth and biomass productivity comparable to the WT under pilot-scale conditions, reinforcing random mutagenesis as a viable and scalable tool for microalgal strain improvement. Ongoing characterization of its biochemical composition and additional pilot-scale trials at higher temperatures will further validate MT009 strain thermotolerance and clarify its robustness and potential for large-scale commercial deployment.

## Introduction

Bivalves harvested or reared in areas with high microbiological contamination require depuration in clean seawater without food for 1–3 days, or longer in relaying facilities, to ensure safety for human consumption[(1)]. However, this starvation period can impair survival, physiological condition, health, and nutritional value, challenging their marketability[(1)]. To mitigate these effects, safe and nutritionally balanced microalgae-based diets for depuration are essential for enhancing bivalve welfare, quality, and producers' revenues. However, the production of live microalgae in hatcheries for bivalve nutrition represents 30-50% of total operational costs[(2)] and poses logistical and technical challenges, driving the pursue for alternative and cost-effective commercial microalgal feed solutions. Microalgae liquid concentrates have emerged as a promising option, offering several advantages such as ready-to-use diets, year-round availability, consistent quality, and nutritionally adequate profiles. However, existing commercial products hinder their application in relaying and depuration since they are not adapted to these aquaculture systems and contain high microbial loads, which can compromise their technical application, as well as feed safety, stability, shelf-life, and bivalve performance. High microbiological loads in diets degrade water quality, disrupt organisms' gut microbiota, and weaken their immune system[(3)]. Therefore, improving the microbial quality of these diets is crucial, especially for depuration, which requires bacteriologically clean water[(1)]. Thermal treatments efficiently reduce the bacterial load in microalgae liquid concentrates, making them promising for use in depuration system diets[(4)]. This study aims to develop a novel microbiologically-safe, nutritionally balanced microalgae diet (DepuraShell) to improve the quality of Pacific oysters (*Magallana gigas*) during depuration, while being technically adapted to Recirculation Aquaculture Systems (RAS). For that purpose, the organism's biological performance was evaluated during depuration and shelf-life storage, focusing on oysters' physiological status.

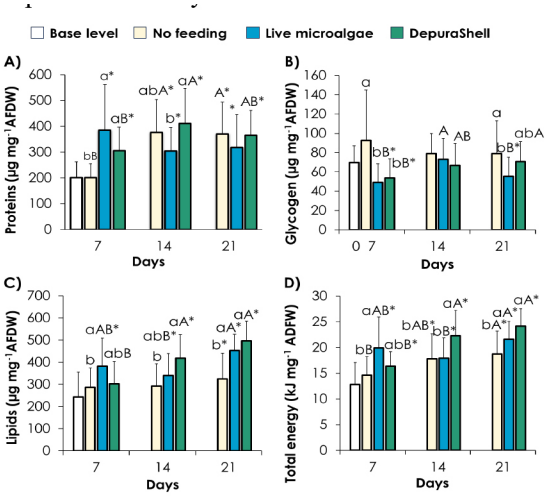

**Figure 1**: *Magallana gigas* oysters proximate composition after 21 days of depuration by dietary treatment (mean ± SD, $n = 20$): A) protein, B) glycogen, C) lipids and D) total energy. Asterisks indicate significant differences from base level (independent samples *t*-test, $p < 0.05$). Lowercase letters show significant differences between dietary treatments at each timepoint, while uppercase letters show significant differences over time within the same treatment (one-way ANOVA, *post-hoc* Tuckey, $p < 0.05$)

*(Continued on next page)*

**Material and Methods**

The previously selected strategy to lower the bacterial load of microalgae liquid concentrates was low-temperature long-time (LTLT) pasteurization (75±2ºC, 1h, followed by a 10ºC cold shock) due to its efficiency in lowering bacteria, without causing cell agglomeration, sedimentation, or degradation of key pigments. The LTLT-treated DepuraShell pilot diet was formulated as a liquid concentrate with 8% algal dry weight (DW), containing *Tetraselmis chui*, fortified with docosahexaenoic acid (DHA), and supplemented with carbohydrate-rich ingredients. LTLT was applied to the diet and frozen until its usage. A 28-day trial was conducted in three closed 250L depuration modules with ultrafiltered and UV-treated recirculating seawater (15°C, salinity 35), each equipped with a protein skimmer. Oysters (*n*=354) were assigned to three feeding treatments: (1) live microalgae (*Tisochrysis lutea* + *Tetraselmis* sp., 3:2 ratio; (3% of oyster DW (g) in algal DW (g)/day), (2) LTLT-treated DepuraShell diet; (8% of oyster DW (g) in diet DW (g)/day), and (3) an unfed control. Oysters were fed twice daily for 21 days, followed by 7 days of storage at 4°C (shelf-life simulation). Daily survival was recorded, *Escherichia coli* levels (Most Probable Number, MPN) were quantified at 0 and 18h, and weekly assessments included condition index (CI), proximate composition (proteins, glycogen, lipids, total energy), and biometric parameters (wet weight, length, width, thickness). Fatty acids profiles were analysed at day 0, day 21, and day 28.

**Results and Discussion**

Results showed effective depuration in all treatments, with *E. coli* levels dropping from 1300 to <18 MPN/100g within 18h. Survival remained near 100% across all treatments throughout the 21-day trial. Oysters fed with DepuraShell diet exhibited significantly higher shell length (91.26±9.46 mm) and wet weight (74.38±7.86 g) compared to the base level. During this period, DepuraShell also significantly improved oyster's CI compared to the unfed control, with no significant differences compared to live microalgae. DepuraShell-fed oysters accumulated significantly higher lipid (496±89.66 $\mu g.mg^{-1}$ ash free dry weight (AFDW)) and total energy reserves (24.14±3.45 $kj.mg^{-1}$ AFDW) at day 21, compared to unfed oysters, mitigating the typical lipid depletion observed in food-deprived bivalves during the depuration process. Glycogen reserves were mobilized in fed groups due to higher metabolic activity, in contrast to the unfed condition, where lower metabolic activity occurred due to the absence of feed. These oysters also exhibited significantly higher DHA and eicosapentaenoic acid (EPA) levels (26.94±0.66; 15.45±0.75% of total fatty acids, respectively), and had significantly higher *n*-3/*n*-6 (9.53±0.72), DHA/EPA (1.75±0.12), and PUFA/SFA (1.85±0.08) ratios compared to the unfed group, making it an excellent alternative to standard depuration without feeding. During the 7-day shelf-life period, survival remained at 100%, and oysters' CI, along with protein, lipid, and total energy levels, were maintained in DepuraShell-fed oysters.

In conclusion, DepuraShell is a nutritionally balanced diet, technically adequate for RAS systems, that enhances *M. gigas* commercial value during relaying and depuration by improving growth, body condition, nutritional quality and fatty acid profile, while guaranteeing microbiological safety for human consumption.

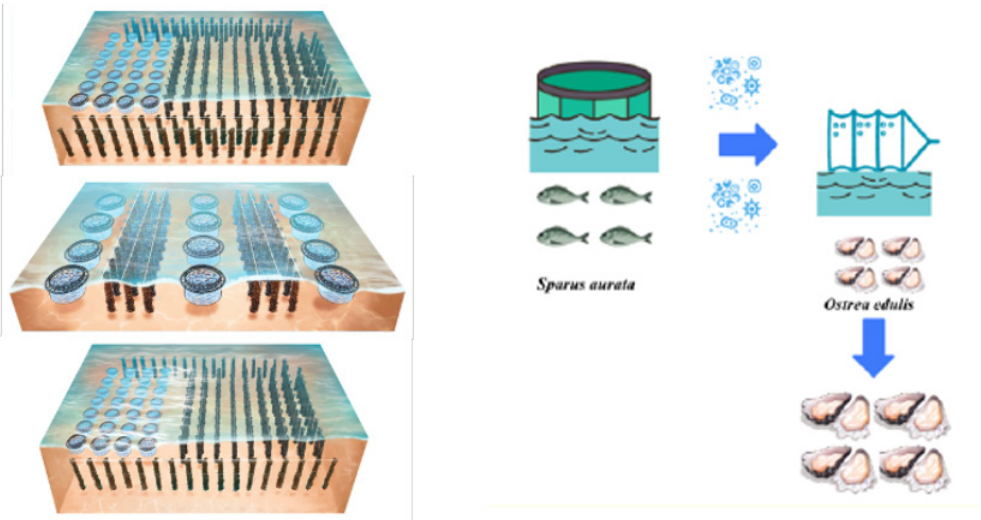
[3]Department of Aquaculture and Fish Diseases, Aquaculture PhD Program Institute of Graduate Studies in Sciences, Istanbul University, 34116, İstanbul, Türkiye
esinbatir@gmail.com

The European flat oyster (*Ostrea edulis*), a filter-feeding bivalve and a high-value seafood product, faces significant challenges in cultivation, including limited production and ecological pressures. To explore its potential in ocean restoration and Integrated Multi-Trophic Aquaculture (IMTA) systems, a 390-day experiment was conducted (February 2023–March 2024) in Gaeta, Italy, in the Tyrrhenian Sea. Oysters were deployed in lantern nets at two locations: 20 m from fish farm cages (IMTA site) and 600 m away (Mono site). Sampling occurred bi-monthly, assessing growth parameters, specific growth rates (SGR), nutritional composition, amino and fatty acid profiles.

Initial mean weights of oysters (28.31±2.00 g), shell length (7.04±0.70 cm) and shell area (23.84±1.36 $cm^2$) increased to 49.41±2.18 g, 8.36±0.05 cm, 34.23±2.69 $cm^2$ in the IMTA site and 52.65±2.76 g, 8.32±0.90 cm, 34.94±1.42 $cm^2$ in the Mono site, respectively. Significant seasonal fluctuations in dry meat weights were observed, with oysters at the Mono site showing notably higher values by the end of the experiment. The specific growth rate (SGR) for shell length was 0.10% and for dry weight was 0.22% in both sites.

Nutritional analyses revealed distinct trends, with the highest protein content measured at 7.81±0.21% and lipid levels reaching a maximum of 1.31±0.05%. The Mono site oysters exhibited higher levels of n-3 polyunsaturated fatty acids (PUFAs) and essential amino acids. Seasonal variations were evident, with dry meat and nutrient levels peaking before spawning in April, declining after spawning in November, and increasing again by March in preparation for the next reproductive cycle.

In conclusion, optimal oyster growth was linked to 600 m distances from fish farm, where phytoplankton availability, enhanced by fish farm-derived nutrients, reached optimal levels. Oysters closer to the fish farm struggled with undiluted organic waste, impacting growth efficiency. Based on our findings and existing literature, we developed three productive models considering local hydrodynamics and nutrient distribution for oyster-IMTA. These models offer valuable guidance for Allocated Zone for Aquaculture (AZA) and Marine Spatial Planning (MSP) policies.



# OPTIMISING THE MEASUREMENT WORKFLOW OF GROWTH PARAMETERS FOR AN UPSCALING MACROALGAE INDUSTRY, INTRODUCING PHIAMPP: A POST-HARVEST HIGH-THROUGHPUT IMAGEJ-BASED ANALYSIS WORKFLOW FOR MACROALGAE PHENOTYPING, UTILISING A PHOTOBOX

Research and Development Centre Kiel GmbH,
Schwentinestraße 24
24149 Kiel, Germany
Jakob1becker@gmail.com

**Introduction:**
Over the past thirty years, the macroalgae industry has developed into the fastest-growing aquaculture production, with an annual biomass output of over 35 million tons of fresh weight. However, similar to agriculture, both quantity and quality yields vary significantly between harvests due to various abiotic and biotic factors (Sugumaran et al., 2022, …). Monitoring the status of the crops and distinguishing between potential causes requires highly frequent and precise monitoring of individual macroalgae blade performances. However, while production and cultivation techniques have evolved into large-scale production, growth assessment methodologies have not advanced at the same rate. Furthermore, analysing a statistically meaningful sample size results in substantial working hours, which is amplified if multiple systems and different strains demand monitoring over multiple time points. Moreover, for other potentially vital parameters, e.g., colour, no standardised methodology exists. This creates an informational bottleneck. The automatic measurement of growth parameters, known as plant phenotyping, is a wellestablished field in botany and agriculture. Its importance for the scaling of macroalgae production lines in microscopic and macroscopic stages has been well identified (Overrein et al., 2024, Dishon et al., 2024). First attempts to transfer established imaging technologies to aquatic plants have been conducted for area estimations, percentage calculations, the status of cultures (Overrein et al., 2024) or heat-induced stress on blades (Gonzales et al., 2025, …). While these approaches utilise parts of the image analysis toolkit, there is, to our knowledge, no comprehensive, user-friendly and efficient workflow published for the commonly used ImageJ/Fiji platform, which automatically measures even fundamental growth parameters of individual macroalgae blades and therefore strains. Here, we describe a methodology for both hardware and software, which establishes a semi-automatic analysis for post-harvest samples, utilising in-house developed ImageJ/Fiji, Excel/VBA scripts and standardised light settings. Altogether, these compounds combine existing functionalities in a novel manner to accurately measure relevant growth parameters such as colour, blade area, maximum width and length, per macroalgae blade, for hundreds of macroalgae in one image, while cutting working hours in half.

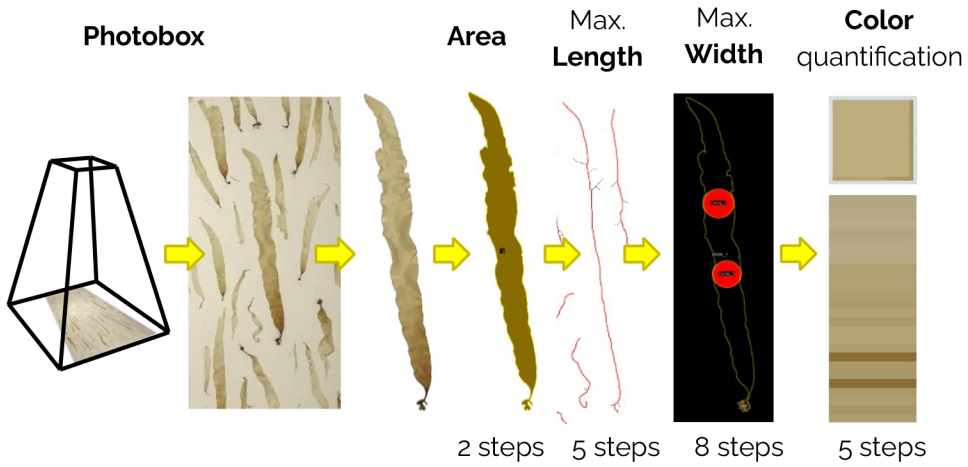

*Figure 1: Workflow of the semi-automatic measuring system PHIAMPP. The setup enables blade-specific measurements of area, width, length and colour. The frequency distribution (top 25 tones) of the blade colours can be visualised as an average, barcode as well as numerically, in HEX and RGB values.*

*(Continued on next page)*

**Methodology:**
**Manual** workflow: … After the harvest of at least 100 individual blades of macroalgae, per length of cultivation substrate, the algae are cooled if not processed immediately. For the picture taking, the algae blades are placed manually onto a white background underneath the custom-built photo box. Length and/or colour scales, as well as metadata, are included.

**Digital workflow:** … custom-written scripts for ImageJ/Fiji and Excel/VBA have been in-house developed to automate almost all necessary steps to measure and visualise the parameters of interest (blade area, maximum length, maximum width and RGB colour), with minimal observer interaction. …

**Discussion:**
While subtle variations in area, length and width were observed, no significant differences between the distribution of the manual and digital datasets were found, indicating a similar precision between the two approaches. This approach enables unprecedented measurements of currently unutilized parameters, such as the quantification and processing of blade colour under standardised light regimes. The workflow has been applied to parts of the *Saccharina ssp*. harvest of the aquaculture research project ULTFARMS, which results in the establishment of a common image database between geographically distant production sites. This increase in standardised image-based data sets will enable further development of advanced algorithms to expand the automated measurement of other relevant, more complex parameters, such as rhizoid width, sorus quantification. Within the near future, we envision a technological advancement in marine plant phenotyping, with similar success as it has been shown for land plants. Further methodological progress will undoubtedly benefit various fields of research in phycology, as it allows for insight into growth patterns relevant for plant health monitoring, pest management and strain performance.

# OPTIMIZATION OF PHLOROTANNIN EXTRACTION FROM *Cystoseira compressa* USING DIFFEERENT EXTRACTION METHODS

K. Begić[a]*, O. Malev[a], S. Radman[b], S. Babić Brčić[a]

[a]Ruđer Bošković Institute, Bijenička cesta 54, Zagreb, Croatia
[b]Faculty of Chemistry and Technology, Split, Croatia
E-mail: kbegic@irb.hr

## Introduction

Phlorotannins are a unique group of polyphenolic compounds, biosynthesized by brown macroalgae (Phaeophyceae) as part of their ecological defense strategies. Built from phloroglucinol monomeric units, they exhibit remarkable structural diversity through different types of linkages and degrees of polymerization, resulting in a wide range of molecular weights and biological activities (Fernando et al. 2022). These activities include potent antioxidant, anti-inflammatory, antimicrobial, antiviral, algicidal effects (Lemesheva et al. 2023), which have attracted considerable attention due to possible uses in the cosmetics, pharmaceutical and nutraceutical sectors. Despite this potential, reliable quantification and bioactivity assessment of phlorotannins remain challenging due to the absence of standardized extraction/fractionation methodologies. Variation in solvents selection, pH adjustment, antioxidant use, and purification techniques contribute to inconsistent yields and hinder significant comparisons between studies.

## Materials and methods

This study aimed to systematically compare and optimize five commonly used extraction protocols for isolating phlorotannins from *Cystoseira compressa*, a brown macroalga abundant in the Adriatic Sea. The protocols varied in solvent composition (methanol:water 1:1 v/v with or without pH adjustment), the inclusion of antioxidants such as ascorbic acid to prevent oxidative degradation, pre-extraction with non-polar solvents to remove interfering lipophilic compounds, and the use of solid-phase extraction (SPE) with three sorbent types (Sep-Pak C18, Oasis MCX, Oasis PRIME HLB) to improve selectivity (Lopes et al. 2018; Sardari et al. 2020; Turković et al. 2023). Phenolic content, used as a proxy for phlorotannin concentration, was quantified using the Folin-Ciocalteu assay (Torres et al. 2024).

## Results

Extraction efficiency varied significantly among the tested protocols, with total phlorotannin content ranging from $4.29 \pm 0.014$ to $8.52 \pm 0.045$ mg phloroglucinol equivalents (PGE) per g dry weight (DW). The highest yield was achieved using Oasis PRIME HLB SPE following acidified methanol:water extraction (pH 3), while methods lacking pH adjustment or antioxidant addition generally yielded lower concentrations. The results underscore the influence of pH control, antioxidant protection, and SPE sorbent selection in maximizing recovery and purity of phlorotannin-rich fractions.

## Discussion

This study shows that pH adjustment, antioxidant addition, and SPE sorbent choice strongly influence phlorotannin yield and purity from *Cystoseira compressa*. The highest yield (8.52 mg PGE $g^{-1}$ DW) was achieved with acidified methanol:water extraction (pH 3) and use of Oasis PRIME HLB SPE columns, likely due to improved compound stability and reduced oxidation. These findings align with previous research highlighting the role of controlled extraction conditions in preserving phenolic integrity and maximizing recovery. Oasis PRIME HLB exhibited superior selectivity, efficiently retaining target compounds while minimizing co-extracted impurities. By establishing an optimized protocol that maximizes yield, minimizes impurities, and preserves bioactive integrity, this study contributes to the standardization of phlorotannin extraction methods - an essential step toward reproducible research and the development of industrial-scale applications in health-promoting formulations.

## Introduction

The aquaculture industry faces two major challenges, firstly infectious diseases and secondly the high cost of fish feeds. This is especially true for Atlantic salmon (*Salmo salar*). Research has demonstrated high quality, and nutritionally complete feed is linked to improved health of cultured species. Crosstalk between functional feeds and immune responses may be an effective proactive measure to reduce the need for the use of reactive disease management tools in salmon farming, especially in relation to omega-3 oils and associated phospholipids. This study examined how dietary oils impact the immune function and lipid abundance in Atlantic salmon fed three different experimental diets formulated using different oil sources (a) krill oil, (b) southern fish oil and (c) sunflower oil.

## Materials and methods

Following a feeding trial fish were immune stimulated with *Yersinia ruckeri* flagellin (bacterial stimulant), poly I:C (viral mimic) or by PBS (control), for 24 hours by intraperitoneal injection. Lymphoid tissue (head kidney) were used for RNA extraction and analysed for immune gene expression using qPCR to examine the expression of a panel of immune genes reprsenting the pro-inflammatory, anti-inflammatory, antibacterial and antiviral responses. Blood plasma samples from the same fish were analysed for eicosanoids and PUFAs using liquid chromatography-mass spectrometry (LC-MS).

## Results

In flagellin stimulated fish, mostly similar expressions of pro-inflammatory genes were observed in samples fed krill oil diet and fish oil diet. In contrast, anti-inflammatory gene expression was highest in samples fed with krill oil diet. The expression of antibacterial genes was higher in samples fed krill oil diet than fish oil and sunflower oil.

On the other hand, in Poly I:C stimulated samples, pro-inflammatory gene expressions were lowest in samples fed krill oil than fish oil and sunflower oil diets, with anti-inflammatory responses being higher in krill oil fed samples.

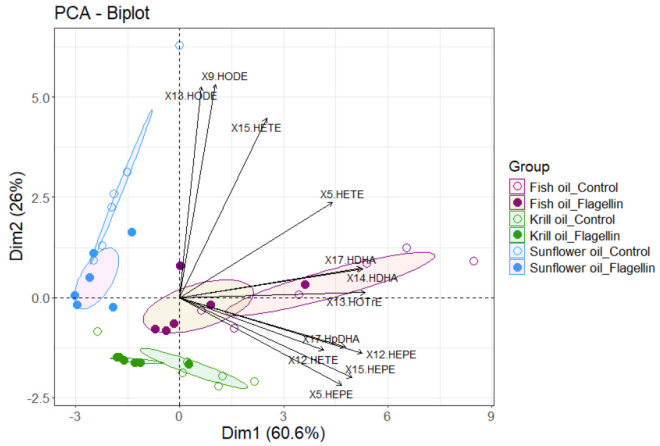

Figure 1: Principal component analysis (PCA) for blood plasma eicosanoids' abundances in control and flagellin stimulated samples

*(Continued on next page)*

In 24-hour post flagellin and poly I:C stimulation, the relative abundances of omega-3 fatty acids (EPA and DHA) and their eicosanoids were lower than control samples. The abundance was observed to be similar in fish oil and krill oil fed samples. In contrast, the abundance of arachidonic acid and its eicosanoids were highest in fish fed sunflower oil diet in case of both stimulations which is responsible for proinflammation (Figure 1).

**Discussion**

In blood plasma samples of fish fed krill oil and fish oil diets, EPA and DHA were used up in a similar way to modulate the immune responses against bacterial and viral stimulation.

Phospholipids (PLs) from marine-based source are rich in omega-3 fatty acids, particularly EPA and DHA. In Atlantic salmon, most of the omega-3 fatty acids come from their diet (Qian *et al*., 2020). Martinez-Rubio *et al.* (2012) compared diets rich in fish oil and krill oil both containing high PL to a diet high in rapeseed oil in Atlantic salmon. After infection with piscine reovirus (PRV) the results showed that fish on marine oil-rich diets had lower viral replication and less heart damage, likely due to a reduced inflammatory response Martinez-Rubio *et al.* (2012).

Overall, the data suggests fish fed diets rich in krill oil may reduce pro-inflammatory responses and induce anti-inflammatory genes in Atlantic salmon which may have benefits for controlling response to pathogens.

## Introduction

Nervous necrosis virus (NNV) is a betanodavirus that affects a wide range of fish species with high economic value. In the Mediterranean area, betanodaviruses belonging to the RGNNV genotype are a serious threat, especially concerning the European sea bass (*Dicentrarchus labrax*) culture. For this reason, the development of prophylactic measures is a priority for the aquaculture industry, encouraging the search of new immunostimulants, such as Growth Hormone-Releasing Peptide 6 (GHRP-6), which is a six-amino acid synthetic peptide that acts as agonist of the growth hormone secretagogue receptor. GHRP-6 has been demonstrated to have immunomodulatory activity in several fish species (Hernández *et al*., 2021; Martínez *et al*., 2022). The aim of this study was to evaluate the anti-NNV activity of GHRP-6.

## Materials and methods

The anti-NNV activity of GHRP-6 was analysed *in vitro*, on E11 cells, by the MTT-reduction assay to quantify the cell survival rate after the viral infection using different approaches (Moreno *et al*., 2023). The *in vivo* antiviral activity was assessed in juvenile European sea bass intraperitoneally injected with GHRP-6 prior to the viral infection (1 $\mu$g/g, 2 doses within 48 h). The transcription of several immuno-related genes was evaluated in head kidney and intestine 24 h after the second injection. At this time, fish were intramuscularly infected with the RGNNV isolate (2 x $10^5$ $TCID_{50}$/g), and the virus was quantified in brain by absolute qPCR (genome quantification) and the $TCID_{50}$ method (infective viral particles) 5 days after the viral challenge.

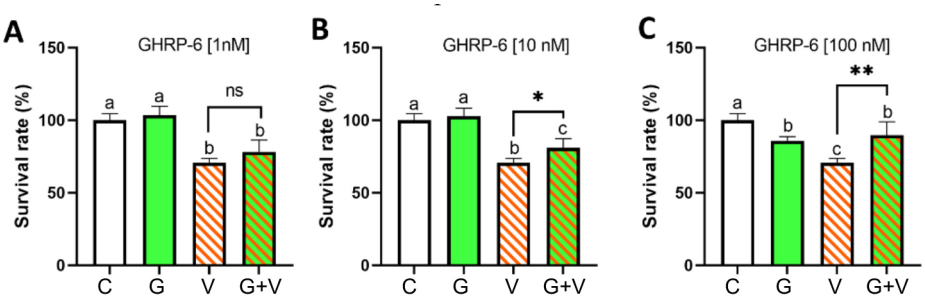

**Figure 1:** Antiviral activity of GHRP-6 against RGNNV in E11 cells inoculated at 0.1 multiplicity of infection (MOI). Survival rate of cells treated with 1 (A), 10 (B) and 100 nM GHRP-6 (C). Control cells (C, white), GHRP-6 treated cells (G, green), infected cells (V, white and red lines), GHRP-6 treated and infected cells (G+V, green and red lines). Data were analysed with the two-way ANOVA test. Different letters denote significant differences. Values of $p<0.05$ (*) or $p<0.001$ (**) were considered significant. Results are mean ± standard deviation (SD) (n = 5).

*(Continued on next page)*

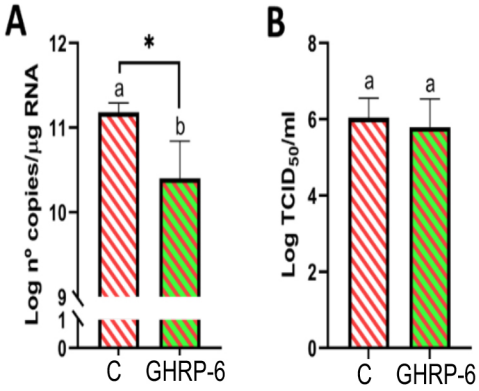

**Figure 2:** Effect of GHRP-6 on RGNNV multiplication in European sea bass brain at 5 days post-infection. (A) Absolute quantification of viral genome. (B) Infective viral particles. GHRP-6 untreated fish (white and red lines); GHRP-6 treated fish (green and red lines). Data were analysed with the two-way ANOVA test. Different letters denote significant differences; $p < 0.05$ values were considered significant (*). Results are mean ± SD (n = 5).

**Results and Discussion**

E11 cells exposed to GHRP-6 for 24 h prior to the RGNNV infection and maintained in contact with GHRP-6 during all the incubation time, were protected from RGNNV (Figure 1). In contrast, other approaches, involving cell exposure to GHRP-6 only before or after virus inoculation, did not result in protection from the viral infection.

Regarding the *in vivo* challenge, gene transcription was evaluated in head kidney and intestine and clear immunomodulatory effects were observed in GHRP-6-injected animals. Furthermore, after RGNNV infection, the number of viral genome copies in brain of GHRP-6 treated animals was significantly reduced at 5 days p.i., compared to untreated fish, although the viral titres were similar in both experimental groups (Figure 2). These results demonstrate a clear antiviral activity of GHRP-6 against RGNNV, and support further evaluation of its antiviral potential against other pathogens relevant to the aquaculture industry.

## Introduction

The gut microbiota represents a complex environment inhabited by a large number of microorganisms that play an important role in numerous physiological processes of live animals, including fish (Singh *et al*., 2025). Indeed, the microbiome present in the whole body, particularly in the gut systems of finfish and shellfish, not only contributes to digestion but also has an impact on nutrition, growth, reproduction, immune system, hereditary traits, and vulnerability of the host fish to diseases. Several factors can influence the gut microbiota structure and composition, including spatial distribution across the digestive tract and time post-feeding. Most microbiome studies target the colonizing autochthonous (resident or adherent) bacteria, as they are considered a more stable population with a more direct impact on the host. However, allochthonous (transient) bacteria may be also relevant with a recognized influence on resident bacteria and host physiology (Viver *et al*., 2023). In any case, the organization of both communities, together with their functional role, still remains far from being clear. Accordingly, this study aimed to assess how the gut autochthonous and allochthonous bacterial communities change and interact in a spatial and temporal manner in farmed fish, using gilthead sea bream as a fish model of the Mediterranean aquaculture.

## Material and methods

One-year old fish (356±12.8 g) were reared in 3,000 L flow-through tanks (IATS aquaculture infrastructure) under natural photoperiod and temperature conditions in June with water [$O_2$] levels maintained above 75% saturation. Fish were fed with a commercial diet (EFICO 3053, Biomar). At 24-h post-feeding, 10 animals were euthanized and samples of mucus and intestinal contents from the anterior and posterior intestine were collected for analysis of the autochthonous and allochthonous bacteria. Additionally, at 48-h post-feeding, mucus layer samples were taken from other 10 fish. Microbial DNA was extracted, and the 16S rRNA v1-v9 regions were sequenced (ONT MinION device) and processed with an in-house pipeline. Sequences were quality filtered and taxonomically assigned following a custom pipeline using SILVA database. A discriminant analysis (PLS-DA) of gut microbiota composition was made with EZInfo software. A Bayesian Network approach was conducted using the SAMBA tool (Moroni *et al*., 2025). Clusters of nodes connected were identified using the Leiden community detection method. Functional profile was inferred for each cluster using the KEGG database for the pathways functional annotation protocol. Statistically significant differences between abundances and functions in resident and transient bacteria were assessed through a non-parametric Kruskal Wallis test.

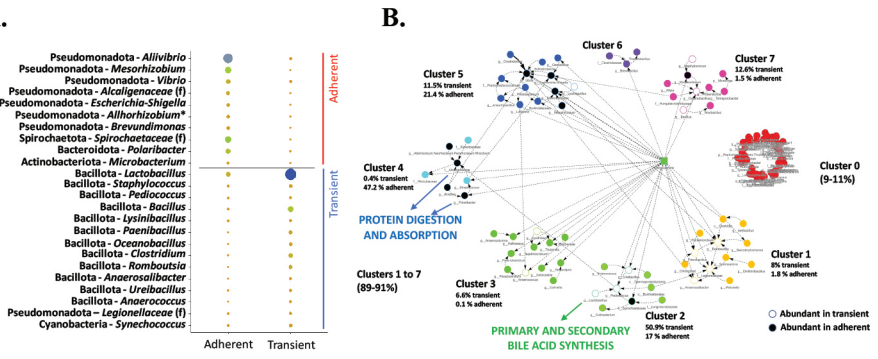

**Figure 1.** (A) Dot-plot showing genera with significantly different abundance between resident and transient bacterial communities and (B) SAMBA Bayesian network displaying clusters of interconnected bacteria and two relevant associated functions.

*(Continued on next page)*

**Results and discussion**

The transient bacteria presented greater values of richness (ACE), either in the anterior (286±83.3) or posterior intestine (276±40.6), in comparison to the gut adherent microbiota considered as a whole (71.2±3.29). Although the diversity indices did not reach a statistical significance, they shared a similar trend (e.g., Shannon index; transient bacteria, 2.09±0.147; resident bacteria, 1.44±0.138). Therefore, in agreement with previous studies (Sommer and Bäckhed, 2013), the mucus layer forms a more restrictive environment that supports the adherence and residence of a more stable microbial population. Besides, while the bacteria phylum Pseudomonadota was dominant in the resident community (47-80%), the Bacillota was the highest represented taxa in the transient microbiota (79-85%). Certainly, the PLS-DA displayed a significant separation between resident and transient bacteria, confirming remarkable variations in their composition. Nevertheless, no clear or smaller differences were observed within each group between anterior and posterior intestinal bacterial communities, or across different post-feeding times. Thus, we focused on the comparison of resident and transient bacteria after 24-h post-feeding, regardless of the sampled intestinal section. At the genus level, most discriminant and abundant bacteria in the adherent community belonged to the phylum Pseudomonadota (e.g., *Aliivibrio, Mesorhizobium, Vibrio,* Alcaligenaceae family*, Escherichia-Shigella, Allorhizobium-Neorhizobium-Pararhizobium-Rhizobium, Brevundimonas*) (Figure 1A). Conversely, in the lumen layer, abundant bacteria were mostly of the phylum Bacillota (e.g., *Lactobacillus, Staphylococcus, Pediococcus, Bacillus, Lysinibacillus, Paenibacillus, Oceanobacillus, Clostridium, Romboutsia, Anaerosalibacter, Ureibacillus, Anaerococcus*). Numerous metabolic functions (147) were associated to both microbial communities, while 54 and 44 pathways were more represented in the resident and transient bacterial communities, respectively. Accordingly, the SAMBA tool allowed to discern different bacterial clusters (Figure 1B) that reveal different links and functional synergies between specific bacteria across the two microbial gut communities. For instance, the Protein digestion and absorption appears likely linked, among others, to family Alcaligenaceae or the genus *Polaribacter* of the mucus layer. At the same time, the Primary and Secondary bile acid synthesis became specially related to some lumen bacteria taxa, including several species of the genus *Lactobacillus* (Ridlon *et al*., 2006).

**Conclusions**

Autochthonous and allochthonous bacteria form distinct communities in the gut of gilthead sea bream. Several genera inhabit both the mucus and lumen layers, but most of them are differentially represented and interconnected. Thus, mucus-associated microorganisms appear essential to preserve gut function, including digestion processes, but at the same time bacteria of the lumen layer becomes necessary for the bile acid synthesis, likely modulating the composition of the mucosal bacteria community.

**Funding**

The work was funded by MCIN NextGenerationEU (PRTR-C17.I1) and by Generalitat Valenciana (THINKINAZUL/2021/024), and BreamHOLOBIONT (PID2023-146990OB-I00) project.

## Introduction

Aquaculture production has significantly increased over the past decade, becoming a key component of global aquatic animal production. In a highly competitive market characterized by standardized products, the establishment of a distinct product identity plays a critical role in influencing market success. Product differentiation facilitates the targeting of specific consumer segments and enables producers to achieve price premiums by offering superior quality or distinctive attributes. This strategic positioning enhances market value and supports long-term sustainability and competitiveness within the industry. On this regard, the incorporation of essential oils from aromatic herbs into aquafeeds has gained increasing attention as a natural and sustainable alternative to synthetic additives and antibiotics in aquaculture. These bioactive compounds, derived from plants such as oregano, thyme, rosemary, and basil, exhibit a range of beneficial properties including antimicrobial, antioxidant, anti-inflammatory, and immunostimulatory effects. More specifically, rosemary essential oil (REO), derived from *Rosmarinus officinalis* L. (Lamiaceae), has shown promising potential as a functional additive in aquafeeds due to its rich composition of bioactive compounds such as 1,8-cineole,  -pinene, camphor, borneol, and others. These components possess strong antioxidant, antimicrobial, and anti-inflammatory properties, which can contribute to improved fish health and performance. REO can also be used in aquafeeds to impart desirable flavor characteristics to fish, potentially enhancing the sensory qualities of the final product. Its aromatic compounds, such as 1,8-cineole and camphor, can be absorbed and metabolized by fish, subtly influencing the taste and aroma of the flesh. This flavor modulation is especially valuable in high-value aquaculture species where consumer preference for flavor and freshness is critical. However, the effectiveness of REO in flavor transfer depends on factors such as dosage, duration of feeding, fish species, and lipid content in the diet and available data are still fragmentary. Additionally, REO is prone to degradation when exposed to environmental factors such as heat, light, oxygen, and moisture, which can lead to the loss of its bioactive properties over time. To overcome these delivery/stability issues, a natural-based microencapsulation technique has been developed in the present study to enable a controlled application of REO in rainbow trout culture with the aim of assessing fish health and promoting product differentiation in the market by delivering a more appealing and consistent flavor profile to consumers.

## Materials and methods

***Rosemary essential oil isolation:*** A six-hour hydrodistillation of 1 kg dry leaves of wild *R. officinalis* (batch no C-130324-18 produced in 11/2024; Minardi & Figli S.r.l., Bagnacavallo, Ravenna, Italy) was performed to obtain ROE. The EO was recovered through a Clevenger-type glass apparatus. For the chemical characterization, the EO was diluted 1:100 in *n*-hexane and then analysed with an Agilent 8890 gas chromatograph (GC) equipped with a single quadrupole 5977B mass spectrometer (Santa Clara, California, USA). The system was equipped with an autosampler PAL RTC120 (CTC Analytics AG, Zwingen). The chromatograms obtained were studied by using the MSD ChemStation software from Agilent and the NIST Mass Spectral Search Program; linear retention indices (RIs) and analytical standards available in the authors' laboratory were also used for peak assignment. ***Microencapsulation:*** The REO was microencapsulated by STM Aquatrade S.r.l. (Castelraimondo, Macerata, Italy) utilizing a novel technology named Co.M.E. (Coating MadeEasy) based on natural molecules. Microcapsules are able to stick to any aquafeed and deliver their content to the fish.  The provision of 1.5 g of microcapsules corresponded to a net transfer of 25 ppm of the REO to the feed. ***Experimental design:*** 120 adult rainbow trout (400 ± 30 g) were divided into two experimental groups in triplicate: Control and REO group fed a control diet and a control diet supplemented with microencapsulated REO, respectively. Fish were daily fed with experimental diets (0.8% of the body weight) for 90 days. At the end of the trial fish were euthanized to evaluate zootechnical performances and welfare (growth performances; histological analyses of liver and gut; molecular analyses of fish stress and immune responses as well as the effectiveness of REO in flavor transfer in fish fillets).

*(Continued on next page)*

**Results and Discussion**

The chemical composition of rosemary essential oil (REO), as determined by gas chromatography-mass spectrometry (GC-MS), was predominantly characterized by 1,8-cineole (47%), camphor (19%), α-pinene (10%), borneol (5%), α-terpineol (4%), *p*-cymene (2%), and limonene (1%), with other constituents occurring at relative percentages below 1%. The microencapsulation technique developed in this study effectively preserved the integrity of REO and enabled its targeted delivery through aquafeed. No significant adverse effects on fish growth performance or welfare were observed following REO supplementation. Furthermore, evidence of flavor transfer from REO to fish tissue was demonstrated, indicating its potential application in enhancing the sensory quality of aquaculture products.

# WORLD VETERINARY EDUCATION IN PRODUCTION ANIMAL HEALTH (WVEPAH) A WOAH COLLABORATING CENTRE FOR ADVANCED TRAINING IN LIVESTOCK ANIMAL HEALTH "CONTINUING EDUCATION MUST DRIVE FOOD SECURITY FOR ALL"

Alexandre Beljean*, Pierre Cadot

World Veterinary Education in Production Animal Health (WVEPAH)
Belvaux, Luxembourg
Email: alexandre.beljean@wvepah.org

**The situation:**
By 2050, more efficient animal production will be required. The animal production sector faces intense pressure to increase the supply of high-quality, safer food while preserving natural resources and environment.

Human activities have a direct impact on the environment, and governments, civil society and consumers expect the animal production sector to adopt the best management procedures and mitigation strategies to reduce its impact.

The intensification of animal production has exposed animals to more diseases and is contributing to the development of multi resistant bacteria (AMR), threatening both animal and human health. The interconnections between animals and people have stressed the importance of the One Health approach in addressing the global rise of antimicrobial resistance (AMR).

Therefore, WVEPAH thinks the holistic approach towards increasing the sustainability of animal production is essential for global food security.

While intergovernmental institutions are proposing regulations and standards to improve the sustainability of animal production and fair trade, veterinarians, animal production specialists, and producers need concrete and practical support and guidance.

WVEPAH is training and certifying animal production professionals working closely with producers. These experts work in the private or public sectors, in international institutions or companies acting locally, regionally or globally.

- We strive to provide these experts with the latest knowledge and tools to address health and animal production management in a holistic approach, the only approach for the sustainability of animal production.
- We believe that our experts are valuable partners to help producers:
- Attain the best possible outcome for their production systems, improve animal production, health and welfare in a sustainable manner and produce healthier and safer foods.
- Understand that prevention is the best way to deliver sustainable results.
- Implement health management and biosecurity plans to prevent or detect diseases and emergency situations early, mitigate their impact and reduce the risks of antimicrobial resistance.
- Become more resilient to drastic changes with thorough understanding of optimal health and performance parameters on their farms and regions
- Adopt international standards to make trade smoother and more predictable.

WVEPAH brings a concrete One Health teaching and learning approach to animal production and health for all. Through training and certification, we empower our experts to serve as the ultimate resources for intergovernmental organizations, driving the changes needed to sustainably improve the world's food supply and leave no one behind.

*(Continued on next page)*

**WVEPAH programs: A series of 80-hour modules are available**

The programs target professionals with a veterinary degree or a diploma in agronomic science in related fields.

- The Module I:" Fundamentals" and WOAH Regulations: Teaches the systemic approach of production systems and how to evaluate if the system is threatened: Management of performances, Nutrition and Feeding, Environment, Biosecurity & Health: hygiene, surveillance, AMR management, diseases, Physiology, epidemiology. This module gives professionals strong bases and technical know-how.
- The Module II – "Specialised" delivers teaching focused on specific productions and geographical areas and challenges.

These modules have a hybrid format: On-line followed by a face-to-face 5-day event at one of WVEPAH's host veterinary faculties all around the world, combining lectures and practical sessions, clinical cases review and discussion. Our Course Masters are internationally recognized specialists in their respective fields and participants greatly benefit from their broad practical experience.

**Certifications and Diploma worldwide validated by WOAH**

All participants at WVEPAH modules receive a certification of attendance. Participants who successfully completed Modules I and II and submitted 25 clinical cases or a series of farm audits are awarded the Professional Certificate in Animal Health: Poultry, Aquaculture or Swine.

Production by the University of Montreal and validated worldwide by WOAH. This post-graduate degree confers de facto to their recipients the status of International Expert in Aquaculture health management.

**Achievements and Future objectives**

We have several hundred certified experts around the World. WVEPAH will be a main institution recognized for providing up-to- date, global knowledge, training experts to ensure Food security for all, humans and animals alike. The next Aquaculture training sessions for 2026 will be held in France and Singapore.

# MICROBIOLOGICAL QUALITY AND SHELF LIFE EXTENSION OF REFRIGERATED NILE TILAPIA (*Oreochromis niloticus*) FILLETS SUPPLEMENTED WITH *Artemisia annua*, ARTEMISININ, AND ARTEMETHER

## 1. Introduction

Fish are vulnerable to microbiological and chemical deterioration due its intrinsec factors such as high-water activity, neutral pH and high content of polyunsaturated fatty acids (PUFAs) (Santos et al. 2017). Food quality is assessed by microbiological analyzes and postmortem changes that alter sensory and physicochemical characteristics (Aracati et al., 2022). During storage, they undergo lipid oxidation, affecting their sensory characteristics and nutritional quality (Rodrigues et al., 2025). Nile tilapia (*Oreochromis niloticus*) is highly perishable, and preserving its quality during storage is critical for reducing food waste and meeting nutritional demands. This study explores a sustainable approach using dietary supplementation with *Artemisia annua*, artemisinin, and artemether, natural compounds with antioxidant and antimicrobial properties.

## 2. Material and Methods

A total of 160 tilapia were randomly assigned to four treatments: control (no additive), 1% *A. annua* powder, artemisinin (9.6 mg/kg feed), or artemether (9.6 mg/kg feed). After 30 days of feeding, 320 fillets were collected and stored under refrigeration at 4 °C. Samples were collected and analyzed at four different time points: immediately after slaughter (day 0), and then on days 7, 15, and 30. For each treatment group,10 for microbiological evaluations, which included counts of mesophilic and psychrotrophic bacteria, molds and yeasts, sulfite-reducing Clostridium, Enterobacteriaceae.

## 3. Results

The MPN results for thermotolerant coliforms showed no significant differences ($p \geq 0.05$) among treatments. However, total coliform counts were significantly reduced in fillets from fish treated with artemether after 30 days of refrigeration. Mesophilic and psychrotrophic counts at 7 and 30 days of storage were significantly lower ($p < 0.05$) in treated groups, particularly artemether, compared to controls. Although all groups showed significant microbial growth ($p < 0.05$) over the 30-day shelf life, the increase was more pronounced in the control group. Enterobacteria counts were significantly lower in fish treated with artemether or artemisinin after 7 days of refrigeration; however, counts increased over time in all groups.

No significant differences were found between treatments for mold and yeast counts, although all groups showed an increase after 15 days of refrigeration. Sulfite-reducing bacteria counts showed no significant differences ($p \geq 0.05$) between treatments, with no growth observed. Coagulase-positive staphylococci counts were significantly higher ($p < 0.05$) in control fillets at 15 and 30 days compared to treated groups, with increases over time in both control and Artemisia annua-treated fish.

## 4. Conclusion

The results of microbiological analyzes demonstrate the benefical participation of Artemether, artemisinin and *Artemisia annua* in the shelf-life of tilapia fillets stored under refrigeration. The results of this study revealed that these dietary supplementations were effective in maintaining fish quality and extending shelf life, in addition to having the potential to be used as a food additive due to bioactive compounds.

# OPTIMIZED METHODS FOR WATER-BASED PATHOGEN DETECTION IN AQUACULTURE SYSTEMS

O. Benedicenti*, D.A. Strand, S.N. Mohammad, M.M. Amundsen, H. Sindre, T. Vrålstad

Norwegian Veterinary Institute
Postboks 64, 1431 Ås Norway
E-mail: ottavia.benedicenti@vetinst.no

## Introduction

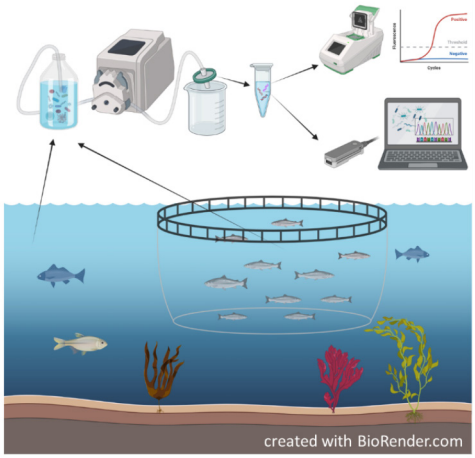
Specific and sensitive tools for detecting and monitoring pathogens in the aquatic environment can be crucial for preventing the spread of infectious agents in aquaculture facilities. Monitoring waterborne pathogens through water filtration and subsequent detection using target-specific (RT-) qPCRs and/or sequencing is an approach that can reduce or even replace the need to euthanize fish for monitoring purposes in aquaculture, allowing earlier biosecurity- and disease control measures.

## Material and methods

We first performed an *in vitro* work where we tested various filtration- and nucleic acid extraction methods for selected pathogens prior to target-specific (RT-) qPCRs to simplify and facilitate on-site water filtration without compromising detection probability. This was tested in combination with different filtration rates, lysis buffers, and filters for freshwater and seawater spiked with relevant salmon pathogens. The suitability and feasibility of the methodology was then tested in the field, where a fish group was followed over time from the hatchery to offshore Atlantic salmon aquaculture facilities until slaughter. Additionally, the third generation sequencing approach (MinION Oxford Nanopore Technologies) was used to correlate shotgun metagenomics sequencing for microbiome analyses to events in the production cycle.

## Results

The results showed that a "sandwich" filtration method combining two different filters allows for the detection of various pathogens with a single filtration step and a single nucleic acid extraction step, followed by (RT-) qPCRs. This reduces both the costs and time required for analysis. Moreover, we showed that this methodology is feasible and effective under field conditions. This means that aquaculture facilities could implement these methods on-site, ensuring timely and accurate pathogen monitoring. Additional shotgun metagenomics sequencing for microbiome analyses with the MinION allowed a microbial screening technique which would lead to future real-time acquisition and analysis of data in the field. This dual qPCR-sequencing approach will provide a unique system to gain knowledge on the impact of real-time monitoring to detect various pathogenic specimens (e.g., viruses, bacteria, parasites).



# CLOSING THE LOOP: IMTA INGREDIENTS AS A SUSTAINABLE PATHWAY IN FISH FEED

**Introduction**

Aquaculture is one of the fastest-growing food production sectors, but it also faces increasing scrutiny due to its environmental impact—particularly the high carbon footprint associated with aquafeed production. As the demand for seafood rises, there is an urgent need to reduce the industry's environmental burden by identifying low-carbon or carbon-neutral alternatives to conventional feed ingredients. One promising yet underutilized solution lies in the use of materials derived from Integrated Multi-Trophic Aquaculture (IMTA) systems (Rusco et al., 2024). These systems produce nutrient-rich by-products that can be repurposed as sustainable feed ingredients, turning waste into value while closing resource loops (Masi et al., 2024). The utilization of IMTA-derived ingredients not only helps lower the carbon footprint of aquafeed but also supports a broader transition toward a more circular, resilient, and eco-friendly aquaculture industry. Among the most promising IMTA-derived candidates for sustainable feed are species such as polychaetes and seaweed, which offer both nutritional value and carbon mitigation potential:

- Polychaetes (*Sabella spallanzanii*): A carbon-sinking polychaetes species cultivated in IMTA on long lines (Arduini et al., 2023).
- Seaweed (*Ulva lactuca*.): commonly used as a "biofilter" in IMTA and reach in protein and lipids, widely utilized as aquafeed ingredients (Shpigel et al., 2017):

This study investigates the potential of incorporating these IMTA produced ingredients into the diet of juvenile seabass (*Dicentrarchus labrax*), aiming to supports the development of circular food systems that can enhance the resilience and economic viability of aquaculture operations.

**Materials and Methods**

This trial was conducted at the Laboratory of Aquaculture, Department of Veterinary Medical Sciences, University of Bologna (Cesenatico, Italy). Juvenile seabass (*Dicentrarchus labrax*; initial average weight 5 ± 2 g) were sourced from Panittica Italia and acclimated for two weeks. Fish (n= 100/tank) were randomly stocked into nine 450 L square tanks (three replicates per dietary treatment) and reared for ~30 days. Tanks operated within a closed recirculating aquaculture system (RAS) equipped with mechanical sand filtration, ultraviolet lights, and a biofiltration as described by Parma et al. (2023). Water parameters were maintained at 24 ± 1.0 °C, 25 ± 5.0 g/L salinity and oxygen levels at 8.0 ± 1.0 mg/L using a liquid oxygen system. Feed was produced at the University of Almeria and the ingredients have been directly collected by an experimental IMTA plan located at Marina Grande (Taranto). Fish were fed 4 different pelleted isoproteic and isolipidic diets:

- Ctrl: 20% FM + 5% shrimp/krill meal
- Diet 1: 20% FM + 5% Sabella meal
- Diet 2: 20% FM + 5% Sabella meal + 5% Ulva meal
- Diet 3: 20% FM + 5% Sabella meal + 10% Ulva meal

Feeding was performed to satiation with a 10% surplus twice daily (8:30 and 16:30) six days per week. At the beginning and end of the experiment, all fish are anesthetized or euthanized with tricaine methanesulfonate (MS-222). Growth performance and whole-body and dietary proximate analyses parameters are calculated. Gene expression related to digestion (*amyl, lip* and *pept*), appetite (*pomc a, ghrl, cart*), growth (*gh, igf1*, oxidative stress (*sod* and *cat*), immune related genes (*il1β* and *il10*) and physiological stress (*hsp70* and *hsp90*) are analyzed to evaluate the nutritional and physiological response to the different diets. All experimental procedures were approved by the Ethical Scientific Committee for Animal Experimentation of the University of Bologna (ID 113/2020-PR), following European Directive 2010/63/EU.

*(Continued on next page)*

**Figure 1:** Specimen of *a*) *Sabella spallanzanii and b) seaweed Ulva lactuca from IMTA in Marina Grande of Taranto;*

**Results and Discussion**

Preliminary results suggest that the inclusion of *Sabella spallanzanii* and *Ulva lactuca* in the diet for juvenile seabass do not have negative effects on growth performance and biochemical composition of fish. This is because both Sabella meal And Ulva meal are rich in high-quality proteins containing essential amino acids required for growth and development, and these proteins are highly digestible. Furthermore, an increase in feed intake (FI) and the expression of genes related to appetite regulation (*ghrl* and *pomca*) is observed due to the known high palatability of *Sabella spp*. Additionally, *Sabella* spp. as well as Ulva contain bioactive compounds such as peptides and polysaccharides that have immune-boosting properties, as observed from the upregulated expression of *il10* and reduced *hsp70*. However, large-scale production and harvesting of *Sabella* spp. may involve high costs, potentially impacting the feasibility of its inclusion in commercial aquafeeds. Despite these challenges, when properly managed, dried *Sabella* meal in combination with Ulva meal can promote growth, enhance feed palatability, and boost immunity due to their superior protein quality, beneficial lipids, and rich mineral content.

# MULTI-USE LOW-TROPHIC AQUACULTURE, OFFSHORE WIND, OR FISH FARMING: EXPANDING the OLAMUR PROJECT FROM THE BALTIC/NORTH SEA TO THE BLACK SEA, THE MEDITERRANIAN AND THE ATLANTIC

Øivind Bergh*, Antonio Aguera Garcia, Marie Maar, Annette Bruhn, Wolf Isbert, Marianne Thomsen, Jun She, Joanna Staneva, Dorothy Dankel, Emily Cowan, Giulia Dapueto, Antonio Novellino, Beatrice Scotto, Rocio Castano Primo, David Bassett, Pamela Ernstberger, Jonne Kotta, Georg Martin, Jack Royd Hall, Anita Jacobsen, Tiril E. S. Johnsen, Bela H. Buck

*Oeivind.bergh@hi.no

The urgent need for more efficient use of marine area, and for European energy and food security, has highlighted the potential for multi-use, i.e. the use of area for more than one purpose. The recent expansion of offshore wind power has emphasized conflicts among different stakeholders. At the same time, aquaculture of low-trophic organisms, such as bivalves or seaweeds appears an attractive way to increase biomass production. Both activities contribute to urgent European needs, for energy and food security. Bivalves can feed on microalgae and particles, and seaweeds utilize nutrients, such as nitrates, phosphates and $CO_2$. In the OLAMUR project, we are developing initiatives for multi-use involving *low-trophic aquaculture* (LTA) in the Baltic and North Seas. Now, the project is expanding with five Associated regions across different European seas.

*Low Trophic Aquaculture* can improve water quality and ecosystem services. Furthermore, it is an attractive way to produce large quantities of biomass in an eco-friendly way, with low footprint, combined with potential for environmental mitigation of over-fertilization and excess carbon. It adds to a circular bioeconomy. At the same time, it contributes to improve Europe´s supply of biomass, thereby its food security.

The addition of Associated Regions (to the OLAMUR project, implies that five additional case studies will be added to the project. All contracts have now been signed, and the five regions are operational.

The Associated Regions, added to the project in February 2025, are operating in different European waters:

1. Black Sea: Kavarna Municipality, Bulgaria
2. Meditteranean: Adana Metropolitan Municipality, Adana, Turkey
3. Atlantic: Midc Páirc na Mara Dac, Galway, Ireland
4. Atlantic : Município de Viana do Castelo, Portugal
5. Atlantic: The Spanish National Research Council, Galicia Spain

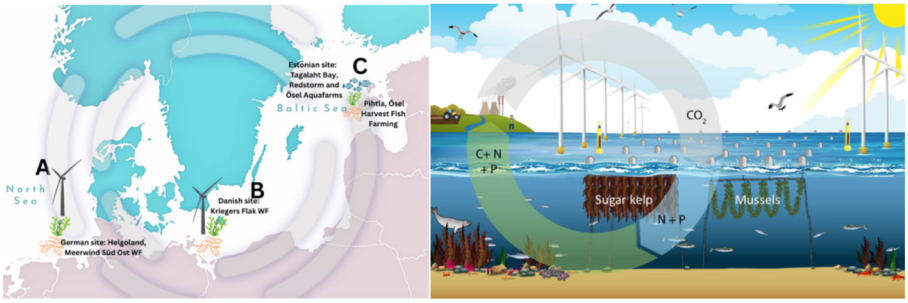

*FIGURE 1 (Left) The three case studies of OLAMUR, in the North Sea (A) and Baltic Sea (B). In case A (Germany) and B (Denmark), low trophic aquaculture of seaweeds (kelp and* Ulva*) and mussels (*Mytilus edulis*) are taking place within the areas of ongoing large scale wind farm operation. In case study C (Estonia), low trophic culture (Ulva and mussels) are carried out adjacent to a rainbow trout farm.*

*(Continued on next page)*

These projects in the Associated Regions are highly different with regards to TRL level. Common to them all is an emphasis on stakeholder mapping and analysis. Offshore wind are in place in some, but not all, Regions. Furthermore, the aquaculture activities are highly different, and the potential is different, due to variations in environmental and societal conditions. The Associated Regions will be integrated in OLAMUR project throughout the remaining life cycle of the project, and provide reports together with the main project and in collaboration with it.

An extensive Data Management Plan ensures transparent and standardized data capture from all parts of the project, as well as its interoperability towards European Marine data infrastructures (EMODnet and Copernicus Marine) for project data legacy (Scotto et al. 2023)

# URGENT NEED FOR MARINE SPATIAL PLANNING OF THE NORWEGIAN EEZ EMPHASIZED BY EXPANSION OF OFFSHORE AQUACULTURE, OFFSHORE WIND, AND OTHER INDUSTRIES

Øivind Bergh*, Solfrid Sætre Hjøllo, Mari Fjalstad Jensen, Anne D. Sandvik, Per Arne Horneland, Marte Louise Strømme, Øivin Aarnes, Bente Pretlove, Caryl Benjamin, Mari Vold Bjordal Sigurd Solheim Pettersen

*Oeivind.bergh@hi.no

Europe´s need for increased energy and food security has been emphasized by the Ukraine war, and the weakening of the Trans-Atlantic alliance. Europe imports 70% of its seafood, and even with the inclusion of Norway, Iceland and the Faroes the continent is heavily dependent on import from outside Europe. To a large degree this is also the situation with energy, where the import of oil and gas from Russia must be replaced by non-European sources. Energy security and food security may be viewed as equally critical in a European as well as a global geopolitical context. Also, to counteract global warming, to adapt to a changing environment, and to facilitate $CO_2$ emissions reduction, there is an urgent need to upscale renewable energy production (Maar et al. 2023).

Pressure is increasing for more extensive utilization of marine areas. This is especially true in the coastal zone (Bergh et al. 2023), but is becoming more evident in offshore environments. This requires careful study of the impact each industry has on its environment and on local communities, considering the cumulative effects from all industries combined. Careful consideration of uncertainties will be crucial to reduce the considerable trust gap among ocean stakeholders, such as fishermen, shipping industry, environmentalists, aquaculturists, and the renewable as well as fossil energy industries.

It should be emphasized that the Norwegian EEZ already is heavily exploited by fisheries and the oil/gas industry. As Figure 2 shows, especially the North Sea, but also the continental shelf towards the Norwegian Sea, and the shallower Barents Sea have a range of oil/gas installations, and in conclusion, the expansion of "new" offshore industries are further emphasizing the need for Marine Spatial Planning (MSP) in the Norwegian EEZ (Pettersen et al. 2024). Careful consideration on the need for marine protected areas (MPAs) should in particular take into account important ecosystem services, as spawning areas and specially vulnerable areas, coral reefs and migration areas for fish juveniles.

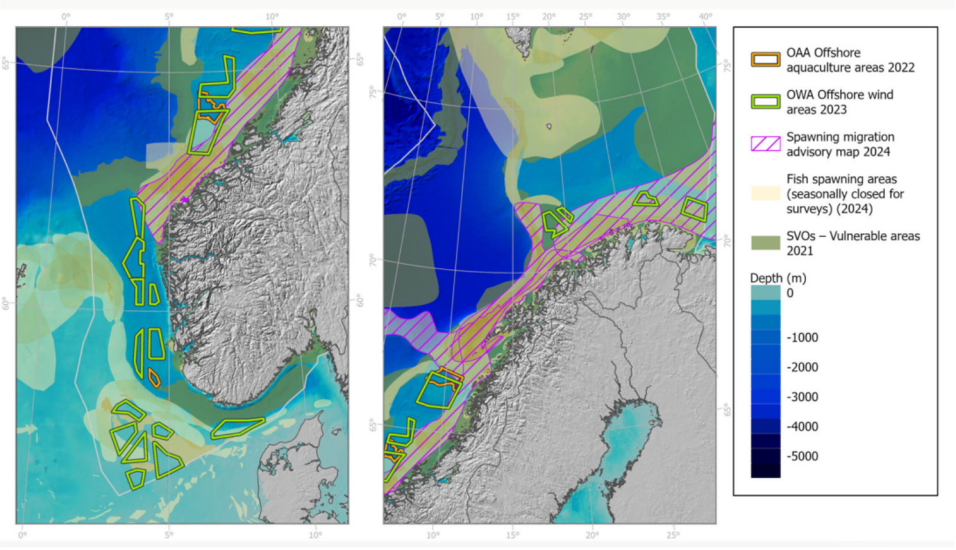

*FIGURE 1 Suggested area for offshore wind and offshore aquaculture, by the Norwegian Ministry for Energy and the Ministry for Industry, trade and Fisheries, respectively. here, the suggested areas are superimposed on the SVO (Specially vulnerable areas) and the fish spawning areas and migration areas for juvenile fish, as mapped by the Institute of Marine Research.*

# DOES NUTRITIONAL PROGRAMMING INFLUENCE ATLANTIC SALMON (*Salmo salar*) RESPONSE TO MICROALGAE IN FEEDS?

Maria Bergvik[1]*, Joana Pedro[1], Charlotte Volpe[1], Eirik Svendsen[1], Andreas Hagemann[1] and Tom Ståle Nordtvedt[1]

[1] Department of Fisheries and New Biomarine Industry, SINTEF Ocean, Brattørkaia 17C, 7010 Trondheim, Norway

Email: maria.bergvik@sintef.no

## Introduction

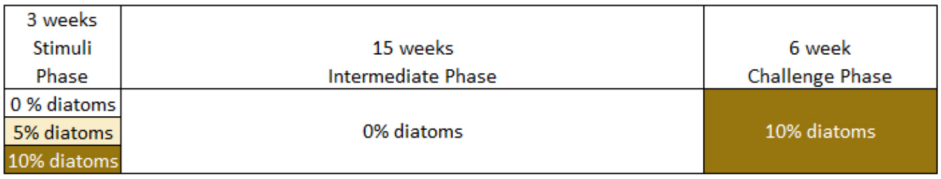
There is a need for more sustainable feed ingredients for farmed animals and Norway has a future goal that "all feed for farmed fish and livestock shall come from sustainable sources and contribute to reducing greenhouse gas emissions in the food system". Microalgae is a promising candidate as a feed resource and in this project a marine diatom that grows fast, contains high amounts of DHA and EPA and all essential amino acids (Artamonova et al., 2017; Jónasdóttir, 2019)Coscinodiscus concinnus, Porosira glacialis, and Chaetoceros socialis, were cultivated in nutrient replete growth medium and harvested in the exponential growth phase. Cultivation took place at temperatures similar to ambient late spring bloom temperature (7 °C will be studied as a feed ingredient for Atlantic salmon (Salmo salar).

Nutritional programming is a field of research that in mammalian studies have focused on suboptimal early nutrition and predisposition of metabolic diseases later in life, while in fish there are documented effects on growth, survival and nutrient metabolism (Clarkson et al., 2017; Hou and Fuiman, 2020)such as permanent growth retardation and impairment of neural development and key metabolic pathways. This phenomenon, termed nutritional programming or metabolic programming, is beginning to be studied in fishes. Despite important differences in maternal nutrient delivery and developmental processes between mammals and fishes, early nutrition of fishes from both endogenous (maternally derived. Some of these documented effects of different live feeds in marine species (Imsland et al., 2006; Koedijk et al., 2010; Øie et al., 2017)a second fed enriched rotifers (RotMG could be explained by altered metabolic pathways and/or epigenetic regulation of gene expression, but there is a lack of studies addressing nutritional programming and long term effects. Previous studies in Atlantic salmon have shown that salmon can be adapted to plant-based ingredients by including these in the starter feed. The feed consumed by the salmon in its early weeks causes long-term changes in gene expression, potentially enabling the fish to better utilize new types of feed ingredients later in production (Clarkson et al., 2017; Sahlmann et al., 2015; Tawfik et al., 2024)fry were fed either a marine-based diet (Diet Mstimulus, 80% fishmeal (FM.

To evaluate the effects of early dietary exposure to diatoms on nutritional programming of Atlantic salmon fry, a 24-week freshwater feeding trial will be conducted, commencing at the onset of exogenous feeding (yolk sac absorption). The trial consists of three distinct phases also shown in Figure 1:

1. **Stimulus Phase (Weeks 0–3):** During the first three weeks, salmon fry will be fed one of three experimental diets containing 0%, 5%, or 10% diatom inclusion. This phase aims to initiate potential long-term changes in gene expression associated with early nutritional stimuli.
2. **Intermediate Phase (Weeks 4–18):** All groups will then transition to a common control diet without diatoms, allowing for assessment of the persistence of early nutritional effects without continued exposure.
3. **Challenge Phase (Weeks 19–24):** In the final six weeks, all groups will be challenged with a diet containing 10% diatoms to assess whether early dietary exposure influences the fish's ability to utilize diatom-based feed ingredients later in development.

*Figure 1: Overview of feeding phases in the 24-week nutritional programming study*



*(Continued on next page)*

This stepwise approach represents a classical model for investigating nutritional programming.

**Material and methods**

Atlantic salmon fry (400-day degrees post hatch) was provided from Aquagen and transported to our facility at SINTEF in Trondheim, Norway. The trial started in 100-liter tanks with flow through fresh water at 8 °C and increased to 11 °C over 7 days with 3 experimental groups and 4 replicas resulting in 12 tanks, with 24h light. Three experimental diets with 0%, 5% and 10% microalgae were produced by Skretting, Norway. In the stimulus phase of 3 weeks, the experimental feeds were fed from the onset of exogenous feeding. In the following intermediate phase, a commercial diet (Skretting) was given and in the last 6 weeks of the trial, during the challenge phase a diet with 10% algae was provided (produced by Skretting). The pellet size of the diets was adapted to the size of the fish using advice from Skretting as a guideline. When the average weight of the fish was about 7 g the fish was pit tagged (Biomark, USA) and transferred to 2 tanks of 4,5 $m^3$ tanks where all groups were mixed until the end of the trial. Fish was sampled after 3 weeks and before and after the challenge phase. Analysis performed was growth, microbiome in gut, gut histology, transcriptome analysis of gut and lipidomic analysis of muscle. At the end of the trial critical swimming capacity was tested in a swimming respirometer and the filet quality was tested with hyperspectral imaging.

All procedures complied with the Norwegian Animal Welfare Act of 20 December 1974, No. 73 (Sections 20–22, amended 19 June 2009). The experiment was approved by the Norwegian Food Safety Authority (FOTS ID 31092).

**Results and Discussion**

Results and discussion will be provided later as the trial is not finalised.

New and sustainable aquaculture systems need to be developed in order to meet the ever so increasing demand for food. In developing countries especially, there is a great need for sustainable yet low-cost aquaculture to provide local farmers with food and income. This study looked at the co-culture of seaweed and sea cucumbers under different conditions, including integrated multitrophic aquaculture (IMTA) systems with oyster and recirculating aquaculture systems (RAS) with milkfish, in Zanzibar, Tanzania. Seaweed production was especially aggravated by the ice-ice disease, resulting in specific growth rates (SGRs) between 1.32 and -1.96 % $d^{-1}$. Nitrogen content in the seaweed thallus and inorganic nutrients in the water showed good results, thus demonstrating the potential of seaweed to be used as a biofilter. An economic analysis showed the economic viability of IMTA systems, co-culturing *Kappaphycus alvarezii*, *Holothuria scabra* and *Pinctada margaritifera*, achieving a maximum benefit-cost ratio (BCR) of 1.61 over one year. Furthermore, interviews with local farmers on Zanzibar showed their willingness to accept new aquaculture systems. However, the farmers also aired a lot of constraints, such as a lack of infrastructure, funds and expertise.

# LARGE-SCALE CRYOPRESERVATION AFFECTS SPERM CHARACTERISTICS AND HATCHING RATE BUT NOT GROWTH, MALFORMATION AND SURVIVAL RATE IN CHUB (*Squalius cephalus*) LARVAE

G. Bernáth, B. Nagy, T. Bartucz, E. Csókás, R. Petényi, I. Bartos, Á. Hegyi, B. Csorbai, B. Ivánovics, J. Molnár, B. Urbányi, Z. Bokor

Department of Aquaculture
Hungarian University of Agriculture and Life Sciences
Gödöllő, Hungary
E-mail: Bernath.Gergely@uni-mate.hu

The objective of this study was to investigate the growth, malformation and survival rate in chub (*Squalius cephalus*) larvae originating from large-scale cryopreserved sperm. Sperm was cryopreserved in accordance with a protocol (modified extender designed for northern pike, 10% methanol, 1:1, 4 mL cryotube, Styrofoam box) previously developed in our laboratory. Firstly, the motility and different kinetic parameters (fresh, control, cryopreserved) of sperm (control and cryopreserved) used for propagation, and the hatching rate were evaluated. Secondly, the growth (average body weight, total length), malformation and survival rate were assessed in a 12-day rearing experiment (0, 8, 12 days post-hatching - DPH) by the larvae originating from control and cryopreserved sperm.

A significantly lower motility (MOT), progressive motility (pMOT), and linearity (LIN) were recorded in the cryopreserved group compared to the fresh and control groups. The distance average path (DAP), curvilinear velocity (VCL), straight line velocity (VSL), beat cross frequency (BCF) showed significant differences in all three groups. The control group (96±1%) exhibited a significantly higher hatching rate in comparison with the cryopreserved group (70±14%). Sperm cryopreservation had no major negative effect on the growth (except only in total length at 0 DPH), malformation and survival rate of chub larvae. Extending the study period to encompass the complete pre-nursing or grow-out periods in future research would be beneficial.

The research was funded by the GINOP-2.2.1-18-2020-00026 grant. Furthermore, our work was also co-financed by the project 2022-1.2.6-TÉT-IPARI-TR-2022-00002 within the framework of the National Research, Development and Innovation Fund announced by the Ministry of Culture and Innovation. This research was also funded by the Ministry of Innovation and Technology within the framework of the Thematic Excellence Programme 2021, National Defense and Security sub-programme (TKP2021-NVA-22). This work was supported by the Research Excellence Programme and the Flagship Research Groups Programme of the Hungarian University of Agriculture and Life Sciences. Our experiments were funded by the EKÖP-MATE/2024/25/K (EKÖP-24-V/MATE-6) university research scholarship Programme of the Ministry for Culture and Innovation from the source of the National Research, Development and Innovation Fund. The study was supported by the project "Support for talent management programmes in colleges" (NTP-SZKOLL-23-0043), commissioned by the Ministry of Culture and Innovation and funded by the National Cultural Fund of Hungary.

# EFFECTS OF BOAT NOISE ON THE BEHAVIOUR AND PHYSIOLOGY OF THE EUROPEAN SEA BASS (*Dicentrarchus labrax*): A FOCUS ON FAMILIARITY AND EXPOSURE PATTERNS

**Introduction**

It is widely recognized that the marine environment is impacted by noise pollution generated by human activities. Maritime traffic is the primary source of diffuse broadband noise in the marine environment, including aquaculture systems, and can have negative effects on marine organisms. Exposure to ship noise pollution can elicit behavioral responses and increase physiological stress in fish and appears to mask acoustic communication with effects on foraging, navigation and reproduction (Popper & Hawkins, 2019). The boat is an essential tool for sea-cage rearing, but it can itself be a frequent and long-lasting stressful factor for the fish that cannot escape. The mode of noise exposure, i.e. gradual or immediate, is also an aspect to be considered in order to have the necessary information to design or apply noise mitigation measures in sea farming but there are few studies that provide information on those aspects.

By combining field monitoring and controlled exposure experiments, the present study aims at assessing the acute noise effects on European seabass stress response and behaviour and the potential effects related to the familiarity of the boat and the sound exposure pattern.

**Materials and Methods**

90 adult European seabass were exposed to boat noise in experimental tanks in groups of five, after elastomer tagging and acclimation. From the acoustic recordings collected at sea, two 30-minute boat noise tracks were selected: (A) the noise from a boat considered "familiar" to the animals, as it was the same vessel that regularly visited the sea cages for the management; and (B) the noise from a boat with similar acoustic characteristics but not experimented by the animals so representing an "unfamiliar" sound to them.

Each tank were exposed for one hour to one of the following 5 noise conditions: background noise of fish farm's origin (BG), familiar boat noise played in a progressive (PF) or sudden pattern (SF), unfamiliar boat noise played in a progressive (PU) or sudden pattern (SU).

After exposure, fish blood and tissues were collected following anaesthetic overdose (MS222, Sandoz) and samples were stored at -20°C until analysis. Cortisol, as main stress hormone, was measured by Radioimmunoassay (RIA) in different matrices (plasma, mucus, fin, and scales) to assess the fish stress response avoiding sampling effects and potential fish chronic stress status before the exposure (Bertotto *et al.,* 2010). Haematocrit as well as plasmatic glucose, lactate and heat shock protein levels (HSP70) were assessed, as secondary stress response indicators, by means of an automatic analyser (BIONSEN, EKF Diagnostics) and a commercial ELISA kit (Cusabio). Physiological indicators were compared across treatments through Bonferroni correction test ($P<0.05$).
Behavioral data was collected on videos, in five non-consecutive 5-min intervals, one before and four during the exposure. DeepLabCut, a machine learning for the markless pose estimation using a deep neural network with supervised learning, was trained to track fish and collect data related to the movements, specifically the swimming speed. Behavioural data were analysed separately for each noise exposure via Generalized linear mixed model, with sampling interval as a fixed factor and the tank as a random factor.

*(Continued on next page)*

**Results and Discussion**

Overall, physiological data showed mild variation across different noise exposure conditions and no stress response. Plasmatic cortisol showed higher levels in the progressive and sudden unfamiliar noise groups (PU and SU) than in the background group (BG, $P<0.005$) and no differences with the familiar boat noise groups, both progressive and sudden (PF and SF, $P>0.05$). The latter were not different from the background group and overall, the levels were well below the basal ones indicating no stress response (concentration <88 ng/ml; Samaras, 2023). Also, the cortisol in fins and scales, indicators of previous and chronic state of stress, showed baseline values albeit with some differences between groups ($P<0.001$; Bertotto *et al.,* 2010; Samaras *et al.,* 2021). Hematocrit, glucose, lactate and HSP70 levels confirmed the absence of variations among groups ($P>0.05$) and non-stress conditions.

The analysis of movement revealed a significant increase in speed following the onset of sound exposure ($P < 0.05$), regardless of the condition, indicating a sudden behavioral response. When considering specific conditions, individuals in the BG group appeared to recover from the initial startle response, exhibiting a gradual reduction in speed over the subsequent hour. This recovery pattern was not observed in the other groups. In the SU group, fish initially responded to the background sound but showed a further significant increase in speed upon the onset of the sudden sound stimulus ($P < 0.05$).

**Conclusions**

Plasma levels of cortisol and swimming speed seem to identify unfamiliarity and sudden exposure as the factors that most affect the stress response in European sea bass exposed to boat noise. Basal levels found in all physiological indicators analysed indicate a lack of physiological response to stress despite significant behavioural alteration related to swimming speed. This suggests a disconnect between immediate behavioural responses and typical markers of physiological stress in the context of noise exposure, which requires further investigation.

# ENHANCING GROWTH AND FEED EFFICIENCY IN FRESHWATER ATLANTIC SALMON THROUGH PARTIAL FISHMEAL REPLACEMENT WITH DEFATTED BLACK SOLDIER FLY MEAL

M. Bézagu*, L. Donati, A. Schuller, E. Kvamme

Innovafeed, route de Chaulnes, Lieudit «Les Trente»
80190 Nesle (France)
Email: marine.bezagu@innovafeed.com

## Introduction

Over the past decade, aquaculture and particularly Atlantic salmon farming have undergone a significant nutritional transition, shifting from a fishmeal-based diet to relying on plant-based ingredients[1]. While this shift has contributed to reduced dependency on marine resources, it has also raised concerns relating to land use, health, gut function, and fillet quality[2,3]. Additionally, the volatility in prices and availability of both marine and land-based raw materials is intensifying the search for novel, sustainable, and functional feed ingredients. Insect meal has emerged as a promising candidate, considered a well-suited nutrient source for salmonids, which naturally consume insects in their riverine habitats[4]. The objective of the study was to determine whether 50% of fish meal content in freshwater phase Atlantic salmon diets could be replaced with partially defatted Black Soldier Fly Larvae (BSFL) meal (corresponding to 10% inclusion of BSFL meal in the diet), and its impact on key performance indicators such as growth performance and feed efficiency.

## Materials and Methods

Defatted Black Soldier Fly Larvae (BSFL) meal from Innovafeed replaced 50% of fishmeal in the test diet (corresponding to a 10% inclusion), which was otherwise iso-proteic and iso-energetic to a fishmeal/SPC control. 100 juvenile Atlantic salmon (17.5g initial weight) per tank (n=4 replicates/diet) were fed to satiation 4 times daily for 8 weeks. Feed intake, growth (initial and final weight, SGR, FCR), mortality, and VSI (5 fish/tank at termination) were measured. All parameters were assessed for normality and homogeneity of variance prior to statistical analysis. Subsequently, comparisons were performed using a Student's *t*-test.

## Results

After eight weeks of study, the highest feed intake was observed in the insect-meal fed group (+ 4%, $p > 0.05$), which also had a higher final weight (+ 5%, $p < 0.05$) compared to fish fed the fishmeal based control. This higher final weight translated into a significantly higher specific growth rate (SGR) for the diet with 10% insect meal (1.44 vs. 1.35, $p = 0.0136$). Interestingly, despite a higher feed intake, there was a trend for the feed conversion ratio (FCR) of the test feed to be better than the control feed (0.91 vs. 0.96, $p = 0.0716$ ). Regarding fish mortality, physiologic state and health , no differences were measured between the control and test groups. More specifically, mortality was below 1% in both groups, and viscero somatic index (VSI) was similar in the control and test groups (14.7 for the control diet and 14.9 for the test diet, with no statistical significance).

## Discussion

The results obtained were particularly interesting in regards to previous studies. The improved growth performance (higher SGR, trend for better FCR) observed in our freshwater salmon trial with a 10% inclusion rate, corresponding to 50% replacement of fishmeal by insect meal offers a contrast to other studies such as Belgit et al.'s, which reported no significant effects at a 60% BSFL inclusion replacing both fishmeal and SPC[5]. As highlighted by Weththasinghe et al.'s meta-analysis, the BSFL inclusion rate and the type and percentage of protein replaced are critical[6]. Additionally, the absence of visceral fat accumulation in our study, unlike at higher inclusion rates (Belgit et al.[5]), further underscores the importance of the inclusion level.

## Conclusion

These findings indicate that a moderate level of insect meal inclusion can effectively enhance growth and feed utilization in juvenile Atlantic salmon reared in freshwater. This overperformance should be considered in the economic evaluation of incorporating insect meal as a sustainable and performance-enhancing ingredient in salmonid aquaculture.

giorgia.bignami@unibo.it

**Introduction**

The function and productivity of RASs (Recirculating Aquaculture Systems) are influenced by abiotic and biotic parameters, particularly water quality and microbiology. Bacterial communities in RAS environment encompass both free-living bacteria in the water column and bacteria colonizing tank surfaces, fish and biofilters (biofilm).

Bacterial biofilms pose a significant challenge in aquaculture, serving as persistent sources of bacterial infections for reared species. Understanding on which material in such closed environment, potentially pathogenic bacteria preferably attach to form biofilms is of fundamental importance with the aim to carry out proper prevention strategies and to control possible sources of disease within the system (Schoina et al., 2022).

In this preliminary study, coupons made by different materials were used as support to simulate the main components of the RAS: fibreglass, steel and PVC. The coupons were placed in a tank with European sea bass (*Dicentrarchus labrax*) during a nutritional trial and subjected to the main qualitative and quantitative analyses of the composition of the cultivable bacteria that inhabit the biofilm formed in the coupons.

**Materials and methods**

The test was conducted in a RAS of 12 tanks of 500 litres each fed with previously disinfected natural sea water. Each tank contained 40 European sea bass (*D. labrax*) weighing approximately 30 grams fed with a commercial diet for juvenile sea bass.

Series of coupons simulating the materials used for RAS were placed inside the tanks in this order from the surface: PVC, fiberglass and steel. They had circular shape and the same diameter (22 mm) and were tied together with a nylon thread. The test was done with 3 sampling time: T0 with the coupons inserted in the water for a week without fish, T1 with the coupons inserted after 3 weeks with fish and T2 after 6 weeks. For each sampling a set of coupons was coloured with crystal violet to verify the presence/absence of biofilm. Another set underwent coupon biofilm disruption and dilution plating in TSA + 1.5% NaCl agar and TCBS agar. After carrying out the CFU/coupon counts, the most representative colonies were identified by Maldi TOF (Bruker).

**Results**

Staining with crystal violet indicates that the biofilm is formed and this happened preferably in fiberglass and steel (Fig. 2).

The bacterial counts appeared non-linear but confirm a higher bacterial load in fiberglass compared to other materials. The most representative colonies were identified by Maldi-TOF and, in addition to environmental *Vibrio* spp., potentially fish pathogenic *Vibrio harveyi* and *Photobacterium damselae damselae* were identified.

Further investigations are necessary to analyse the composition of the biofilm also with metagenomics.

Part of the research was carried out under the National Recovery and Resilience Plan (NRRP), Mission 4 Component 2 Investment 1.4 – Call for tender No. 3138 of 16 December 2021, rectified by Decree n.3175 of 18 December 2021 of Italian Ministry of University and Research funded by the European Union – Next Generation EU. **Introduction**

Plastics provide numerous benefits to many sectors but their persistence in the environment has led to widespread pollution, and as a consecuence, microplastics (MPs) and nanoplastics (NPs) represent a serious threat to ecosystems. Bioplastics, such as waterborne polyurethanes (WBPUs), are being developed as more sustainable alternatives. However, the environmental impact of these new materials, especially in their nano-scale size, remain largely unknown. Interactions between microalgae and plastics are expected in the ocean; however, toxicity patterns are not well established. It has already been reported that differences in the coverage of microalgae species can affect microalgae sensitivity to xenobiotics. Therefore, further research on the impact of plastics including bioplastics such as WBPUs, on microalgae strains with varying structural characteristics is required.

**Materials and methods**

This study aimed to assess the toxicity of three types of biobased polyurethane (PU) nanoparticles: (1) partially biobased PUs or WBPUs, (2) WBPUs synthesized using the organic solvent N-methyl-2-pyrrolidone (WBPU-NMP) and (3) WBPUs partially derived from chemically recycled PET (WBPU-BHET). Types 1 and 3 were tested with (WBPU-3CNC and WBPU-BHET-CNC, respectively) and without nanocellulose (WBPU and WBPU-BHET, respectively) incorporated as an additive. Thus, the nanocellulose by itself (3CNC) was also tested. Additionally, for comparative purposes, a commercial folmulation of WBPU nanoparticles (WBPU Covestro Impraperm DL3746 XP) was also tested. As a result, the ecotoxicological effects of seven different compounds were tested on two marine microalgae species, the scales bearing haptophyte *Tisochrysis lutea* and the naked chlorophyte *Oltmannsiellopsis unicellularis*. Growth inhibition tests (OECD guideline nº 201) were run on microalgae exposed to a concentration range (0.01 to 100 mg/L) of each WBPU type and to the equivalent concentrations of 3CNC (3 $10^{-4}$ to 3 mg/L). Since OECD nº201 criteria were confirmed in a shorter period of time for *T. lutea* than for *O. unicellularis* (48 h for *T. lutea* and 72 h for *O. unicellularis*), production of reactive oxygen species (ROS) and maximum quantum yield of photosystem II ($F_v/F_m$) were studied on *T. lutea* exposed to selected concentrations (0.01, 1 and 100 mg/L) of WBPU nanoparticles and to the equivalent concentrations of 3CNC (0.0003, 0.03 and 3 mg/L).

**Results**

Growth rate of both microalgae was only reduced after exposure to the highest concentration of some of the WBPUs tested: WBPU-BHET altered the growth of both microalgae while WBPU-BHET-CNC only altered the growth of *T. lutea* and WBPU-NMP did the same to *O. unicellularis*. Therefore, the two microalgae species exhibited different sensitivity to WBPU NPs which could have been conditioned by the formation of different size heteroaggregates in the marine microalgae exposure media. ROS production was increased in comparison to controls when *T. lutea* microalgae were exposed to all concentrations of WBPU COVESTRO and to 0.01 and 1 mg/L of WBPU-3CNC as well as to the equivalent concentrations of 3CNC. On the contrary, ROS production was reduced when microalgae were exposed to 1 and 100 mg/L of WBPU-NMP. No effects were recorded in $F_v/F_m$.

*(Continued on next page)*

**Discussion**

Selection of microalgae species that show different structural/morphological characteristics seems crucial for the ecotoxicological assessment of bioplastics such as WBPUs, since different organisms seem to respond differently to the same treatments. The observed variation in sensitivity between *T. lutea* and *O. unicellularis* highlights the importance of considering the composition of nanomaterials as well as species-specific traits, such as cell wall composition, surface charge and size, which can influence interactions with nanoparticle aggregates, especially in marine environments. The significant alteration of ROS production depending on the WBPU type and concentration, indicates that subcellular stress responses can occur even in the absence of growth inhibition or photosynthetic impairment while the lack of effects on Fv/Fm across all treatments suggests that oxidative stress may not necessarily translate into functional damage to the photosynthetic apparatus, at least over such short exposure periods.

**Conclusion**

WBPUs are considered a sustainable alternative to conventional PUs, however, both physicochemical characterization of the materials tested and the biological responses of ecologically relevant species must be integrated into further research to better assess the toxicity of bioplastics, such as WBPUs, and their ecological risks

Email: eider.bilbao@ehu.eus

**Introduction**

Beer is the most widely consumed alcoholic beverage globally, with billions of litres of beer being produced each year. The beer production process is water-intensive and generates large quantities of brewery wastewater (BWW), which must be treated before being discharged into wastewater treatment plants. This poses an economic challenge for small beer-producing companies, which characterize the beer sector in the Basque Country. In this context, microalgae cultivation using BWW has emerged as an alternative to traditional treatment methods, as it enables removing nutrients from the BWW, while also producing value-added microalgae biomass, which currently has various commercial applications.

This study aimed to explore the potential use of a BWW from a small craft beer company, Laugar Brewery (Gordexola, Biscay), as a culture medium for microalgae.

**Materials and Methods**

Based on the literature, the chlorophyceans *Chlorella sorokiniana* and *Acutodesmus obliquus* were selected as candidate species for the study. Two strains of each nominal species were acquired from the Banco Español de Algas for an initial screening. Additionally, a fast-growing non-identified green algal strain isolated from our laboratory was included in the study. The five strains were phylogenetically characterized using 18S rDNA as a marker. Subsequently, in order to select one of the strains for growth assays in BWW, all microalgal growth was evaluated using mineral water enriched with F/2 nutrients as culture medium (48-well microplates; 23 ºC; continuous illumination 100 µmol photons $m^{-2}$ $s^{-1}$). Strain BEA0003, confirmed to be *Chlorella sorokiniana,* was selected for subsequent optimization assays.

Three independent batches of BWW were collected from the first cleaning step of the mash tank. The BWW was stored at two temperature conditions (room temperature and 4 º C) for four weeks ($T_0$ - $T_4$) with samples collected weekly. The samples were filtered (0.22 µm) and subjected to one of the three treatments: sterilization by ultraviolet (UV) light exposure, sterilization by autoclaving or not post-filtration sterilization. Filtered samples from $T_0$ and $T_4$ stored at room temperature without sterilization were analyzed for total organic carbon (TOC), total nitrogen (TN) and pH.

For growth optimization, the effects of several variables on the maximum specific growth rate ($\mu_{max}$) were tested: initial cell concentration, different concentrations of nutrient supplementation ($NaNO_3$, $NH_4Cl$, $NaH_2PO_4$ and F/2 micronutrients), dilution of the BBW with mineral water, and the storage conditions and sterilization conditions of the BBW as previously described. Microalgal growth was monitored via chlorophyll fluorescence using a microplate reader. Finally, under optimized conditions (undiluted BBW supplemented with 110 µM $NaNO_3$), a nutrient removal experiment was conducted using BWW from $T_4$ stored at room temperature without post-filtration sterilization as culture medium. The culture was grown for 7 days, with an initial cell concentration of 5 $10^5$ cells/mL and nutrient removal was assessed by measuring TOC and TN concentrations before and after cultivation.

**Results and Discussion**

Initial identification based on DNA sequences revealed a mismatch between the species label and the actual identity of one strain, highlighting the importance of DNA-based identification when working with microalgae. Strain BEA0003 confirmed as *Chlorella sorokiniana* was selected for further experiments due to its high $\mu_{max}$ ($1.99 \pm 0.08$ $d^{-1}$) under the tested conditions and its ability to grow in suspension.

*(Continued on next page)*

The analysis of the chemical composition of three different BWW batches revealed an appropriate pH (7.3-7.7) but significant variability in TOC and TN along with low nitrogen concentrations. This suggested an imbalance in C/N and N/P ratios, which might limit microalgae growth. This was supported by the observed improvement in growth with nitrogen supplementation, particularly with nitrate. However, no significant differences were found among BWW dilutions or between different nitrate concentrations, with 110 µM identified as the recommended supplementation level. Phosphorus or micronutrient supplementation did not enhance microalgal growth, indicating that this BBW is not limited on these nutrients. Therefore, the findings suggest that the BWW can be used undiluted if nitrogen (110 µM $NaNO_3$) is supplemented, without the need for additional phosphorus or micronutrients. Moreover, BWW stored at room temperature for four weeks ($T_4$), without refrigeration or post-filtration sterilization, significantly enhanced microalgae growth compared to freshly collected BBW ($T_0$). The $\mu_{max}$ values varied significantly across different BBW batches, indicating that variability in chemical composition influenced its suitability as a culture medium for microalgae. Nevertheless, under the defined culture conditions (BWW stored at room temperature, without post-filtration sterilization and supplemented with nitrate), high $\mu_{max}$ values ranging between 1.24 and 1.50 $d^{-1}$ were achieved. Nutrient removal was also successful, with TOC removal between 23.2 and 45.3 % and TN removal between 69.6 and 86.9 %, resulting in a final effluent considered safe for disposal. These results demonstrate that cultivating the chlorophycean *Chlorella sorokiniana* in this BWW is a viable strategy for the valorization and reuse of these wastes, while simultaneously contributing to reduced microalgal biomass production costs and water consumption.

This work was funded by the Basque Government through grants to the consolidated research groups IT1743-22 and IT1723-22, and the Fundación HAZI Fundazioa.

# UNLOCKING THE NUTRITIONAL VALUE OF *Arthrospira platensis* INDUSTRIAL BY-PRODUCT: PROTEIN EXTRACTION AND IN VITRO DIGESTIBILITY

Josep Biosca-Micó*[1], Antonio Martínez-Abad[1], Amparo López-Rubio[1] , María José Fabra[1] , Ever Hernández-Olivas[2] and Laura G. Gómez-Mascaraque[2,3]

[3]BiOrbic Bioeconomy SFI Research Centre, University College Dublin, Dublin 4, Ireland
Email: josep.biosca@iata.csic.es

## Introduction

*Arthrospira platensis* (spirulina) is a cyanobacterium renowned for its rich content of bioactive compounds including proteins, lipids, carbohydrates and minerals. Among its commercially valuable products, C-phycocyanin (a blue phycobiliprotein with antioxidant and anti-inflammatory properties) stands out. However, the industrial extraction of phycocyanin generates a residual by-product biomass that, despite its high protein content, remains largely underutilised. Within a biorefinery framework, this by-product represents a promising resource for developing high-value functional ingredients. This study explores ultrasound (US) and high-pressure homogenisation (HPH) as cell disruption techniques to enhance protein recovery from the residual biomass after phycobiliprotein extraction. Furthermore, the nutritional potential of all *A. platensis* fractions (including raw and by-product residual biomass and the resulting protein concentrates) was assessed. Protein digestibility and bioaccessibility were assessed via *in vitro* gastrointestinal digestion following the standardised INFOGEST protocol, while protein quality was determined using the Digestible Indispensable Amino Acid Ratio (DIAAR), providing a comprehensive assessment of their nutritional value and potential application in food systems.

## Materials and Methods

Proteins were solubilized from *A. platensis* by-product under alkaline conditions. Ultrasound (US) and high-pressure homogenisation (HPH) were applied as cell disruption techniques to enhance the extraction yield, followed by acid precipitation to recover solubilised proteins. The physicochemical properties of the resulting protein concentrates were characterised. Samples underwent *in vitro* digestion according to the INFOGEST protocol to assess digestibility. Protein digestibility was quantified by total nitrogen analysis, free amine measurement via the o-phthalaldehyde (OPA) assay and total amino acid (TAA) determination. Finally, DIAAR values were calculated for each sample to evaluate the quality of the digested proteins.

## Results

Protein extraction yields from the by product biomass reached 49.1% with US and 61.0% with HPH, showing superior efficiency with HPH. Protein content isolate yields were 60.7% (US) and 63.5% (HPH), varying slightly with the disruption method applied.

Raw *A. platensis* biomass exhibited an average protein digestibility of 91%, which decreased to 78% in the HPH-derived protein concentrate, indicating that processing intensity may reduce digestibility. Despite this reduction, nutritional quality remained high; DIAAR values for most essential amino acids exceeded 100% in all samples, highlighting their excellent nutritional potential. Lysine was the limiting amino acid in protein concentrates, with DIAAS values dropping to 68%, below the FAO-recommended 75% threshold. These findings suggest that mild cell disruption techniques can effectively recover proteins from *A. platensis* by-product, whose favorable nutritional profiles support their potential incorporation into food formulations. This valorization strategy contributes to waste reduction and aligns with circular economy principles.

# FUTURE LINES OF STUDY ON BLUEFIN TUNA (*Thunnus thynnus*)

## Introduction

The Atlantic bluefin tuna (*Thunnus thynnus*, ABFT) is one of the most valuable species in aquaculture, but farmed populations experience high and unexplained mortality rates that threaten production sustainability (Ortega, 2015). This mortality remains a major bottleneck to scaling up production, with particularly high and variable losses during the larval and early juvenile phases (Betancor *et al*., 2019). The underlying causes of this low survival are multifactorial, potentially involving nutritional condition, quality and availability of live prey, environmental factors, handling stress, collisions with tank walls, sudden unexplained deaths, and developmental abnormalities, some of which may be associated with physiological alterations and changes in the gut microbiome. Two ongoing studies led by the team at the land-based tuna facility at Mazarrón (ICTS-ICAR, IEO-CSIC, www.icar.ieo.es) address these aspects: one focused on cardiac health and histology, and another on gut microbiota composition.

## Study 1 – Cardiac health

Optimal cardiac health is essential for the sustained swimming and high metabolism of pelagic predators, yet in aquaculture, stressors can impair heart structure and function, reducing performance and survival (Engdal *et al*., 2024). While such effects are well documented in Atlantic salmon, whether they occur in farmed Atlantic bluefin tuna is unknown. Despite its high metabolic demands and reliance on sustained cardiac output (Blanco *et al*., 2020), detailed descriptions of ABFT heart morphology are scarce, with most information extrapolated from other tunas such as yellowfin (*Thunnus albacares*) and Pacific bluefin (*T. orientalis*), which have characterised ventricular anatomy, myocardium composition, and coronary circulation in relation to swimming performance and thermal tolerance (Korsmeyer *et al*., 1997; Shiels *et al*., 2015).

The present study investigates the role of cardiac health in unexplained mortalities in ABFT aquaculture. By analysing ventricular morphology and histology (H&E, Masson's Trichrome) in individuals from wild, fattened, and fully cultured origins, and spanning larval to adult stages, we aim to identify structural or fibrotic patterns associated with captivity. Comparative evaluation of wild and farmed fish will provide baseline descriptions for the species and assess whether observed differences could contribute to mortality events.

## Study 2 – Gut microbiota

The gut microbiome supports nutrient uptake, immunity, and disease resistance (Ringø *et al*., 2016). In aquaculture, diet, density, and environment can reshape communities, especially during early life when larvae acquire microbes from water and prey and immunity is immature, influencing growth and pathogen resilience. As fish mature, microbiota adapt to diet and habitat.

Research on tuna microbiomes is scarce, with existing studies - mainly on wild juveniles and adults of yellowfin (*T. albacares*), bigeye (*T. obesus*), and skipjack (*K. pelamis*) - showing species-, growth-, and environment-driven shifts in gut communities (Gadoin *et al*., 2021; Zou *et al*., 2024; Huang *et al*., 2025). However, larval stages and farmed individuals remain largely unstudied, and no work has compared wild and cultured ABFT across life stages. This gap reflects a broader absence of ontogenetic data in teleost gut microbiome research. This study characterises the intestinal microbiota of *Thunnus thynnus* across life stages and rearing conditions to address a major knowledge gap. We monitored microbial succession in larvae (4 - 25 dph) under different feeding regimes (rotifers, *Artemia*, yolk sac larvae) and sampled juveniles and adults from cultured and wild origins. DNA-based sequencing of anterior and posterior intestinal sections will reveal how age, diet, and captivity shape microbial diversity and composition, identifying patterns potentially linked to health, performance, and survival in aquaculture.

**Outlook**

Both studies address key knowledge gaps in ABFT biology and have the potential to reveal physiological and microbial indicators linked to mortality in culture. The outcomes are expected to guide strategies for improving husbandry practices, reducing losses, and enhancing the sustainability of bluefin tuna aquaculture.

## Introduction

Potential hazardous contaminants have been identified in aquatic environments coming from different anthropogenic sources. Cadmium (Cd) is a trace element commonly found in aquatic systems as a contaminant. It has both natural and anthropogenic sources, such as industrial discharges and agricultural runoff [1]. Cd effects on neurodevelopment and behavior are well established for mammals, while more comprehensive studies of its neurotoxicity on aquatic organisms such as fish, are still missing [1]. On the other hand, Ciprofloxacin (CIP) is a fluoroquinolone antibiotic frequently found in water bodies due to its incomplete metabolism in mammals and its inefficient removal by water treatment facilities [2]. CIP has been associated with genotoxic effects and increased production of reactive oxygen species (ROS), posing aquatic life at risk [3]. Moreover, its growing presence in aquatic environments may alter microbial communities, potentially compromising the gut health of fish and interfering with neuronal functions through the microbiota-gut-brain axis.

This study aimed to elucidate the neurotoxicity of Cd and CIP in juvenile seabass (*Dicentrarchus labrax*) upon chronic dietary exposure (21 days).

## Methods

One month prior to the start of the experiment, fish were randomly distributed into ten 600 L tanks (n = 30 fish per tank). During this acclimation period, all fish were fed a non-treated diet. Experimental diets were prepared following the alcohol evaporation method adapted for the European sea bass [4]. Treatments were as follows: Control (non-treated diet), CIPL (ciprofloxacin 10 mg•kg$^{-1}$ food), CIPH ciprofloxacin (10 mg•kg$^{-1}$ food), CDL (cadmium 100 mg•kg$^{-1}$ food), CDH (cadmium 10 mg•kg$^{-1}$ food). Experimental diets were administered for 21 days, each in duplicate (i.e., two tanks per condition), under the same natural photoperiod and temperature conditions. During the experiment, all groups were fed *ad-libitum*, twice a day. The estimated daily contaminant intake per treatment was CIPH, 0.182 mg ciprofloxacin, CIPL, 0.018 mg ciprofloxacin; CDH, 1.992 mg cadmium, CDL, 0.177 mg cadmium. At the end of the experiment brain samples were taken to undertake a multidimensional approach comprising epigenetics (DNA methylation by EM-seq), transcriptomics (RNA-seq), antioxidant defences and oxidative damage in the brain, neurotransmission (assessed by acetylcholinesterase - AChE) and behaviour. Biochemical endpoints related to the antioxidant defences were assessed including superoxide dismutase (SOD), catalase (CAT), glutathione S-transferase (GST), and glutathione peroxidase (GPx) activities, as well as total glutathione (GSHt) content, while oxidative damage was evaluated by lipid peroxidation (LPO).

## Results and discussion

Exposure to both Cd and CIP resulted in a decrease in brain glutathione levels, potentially making brain cells more susceptible to oxidative stress. Interestingly, a significant reduction in LPO was observed in CIPL fish, whereas a slight increase in LPO was detected in CDH fish. In contrast, SOD activity increased in the brains of CDH-exposed fish, with no significant changes observed across CIP treatments. Increased AChE activity was recorded in the brain of fish exposed to both concentrations of Cd and CIP. This suggests potential disruptions in neurotransmission, as AChE has a crucial role in breaking down the neurotransmitter acetylcholine (ACh). Excessive AChE may lead to reduced ACh levels, which can impair neural signaling.

Both Cd and CIP exposure significantly altered motor behaviour. Overall, a significant reduction in basal locomotor activity

was observed in fish exposed to both Cd and CIP, regardless of their concentrations. This effect was probably related to the observed increase in brain AChE activity. Moreover, a tendency towards increased cohesion was recorded, reaching statistical significance in the CDH group. In addition, all exposed fish showed an increase in the appearance of freezing episodes, typically associated with anxiety-like responses and depressive states.

In summary, the observed decrease in swimming activity, changes in social behaviour and altered exploratory and decision-making behaviours, accompanied by reduced brain glutathione levels and disrupted neurotransmission, clearly indicate a neurobehavioral impact of environmentally relevant concentrations of Cd and CIP. These results suggest that both contaminants may compromise the antioxidant defence system, eventually leading to oxidative stress, and interfere with neural function and behaviour, potentially affecting fish survival and ecological fitness.

Multi-omic analyses are currently underway to further elucidate changes in transcriptomic and DNA methylation profiles, aiming to link molecular alterations with the observed effects on antioxidant defences, neurotransmission, and behavior. This study highlights the neurotoxicity potential of Cd and CIP in fish and points at the need for further investigation into their ecological consequences.

## Introduction

The high stocking densities are normally used to reduce production costs in the aquaculture industry. However, if it is not appropriate for the reared species, it can become a stressor that often triggers chronic responses and negatively affects feed intake, fish metabolism and, at the end, growth. Thus, finding methods to reduce stress and improve welfare status is essential to increase stocking densities during aquaculture production. The use of nutraceutics is presented as a solution to improve fish welfare in aquaculture activity (Hu et al., 2025). This study assesses the effectiveness of a phytogenic additive with antioxidant properties (AquaNeox, TECNOVIT-FARMFaes Ltd.) in the diet of the European seabass (*Dicentrarchus labrax*) juveniles reared at different stocking conditions.

## Materials and methods

Seabass juveniles (n = 480; $w_i = 105 \pm 30$ g) were placed into 200 L-tanks and distributed in four different experimental groups in triplicate, defined as the combination of feeding (with or without AquaNeox supplementation at 0.05 %) and stocking densities. Initial low density (LD) was defined as 5 kg/m$^3$ and high density (HD) as 37 kg/m$^3$. Fish were maintained under controlled temperature and photoperiod and fed to apparent satiation for two months under these rearing conditions. Periodic biometric samplings were performed to determine growth parameters and adjust feeding. At the end of experimental time target tissues were sampled to assess (blood and liver) physiological status.

## Results and discussion

Inclusion of the nutraceutical AquaNeox did not negatively affect fish growth. Histomorphometry analysis revealed a significant reduction in hepatocyte area in fish fed with the additive (Figure 1A), suggesting a reduction in cytoplasmatic content (volume) of hepatocytes. Conversely, hepatic values of metabolites such as glucose, glycogen and cholesterol did not differ significantly between the experimental groups. However, liver triglyceride levels increased significantly in the AquaNeox groups (under LD and HD conditions) ($p < 0.05$; Figure 1B). One possible explanation for this response is that the antioxidant capacity of AquaNeox stimulated liver lipid accumulation due to peripheral lipolysis and subsequent increased uptake of non-esterified fatty acids by liver cells and the esterification of the excess into triglycerides (Du et al., 2008).

Additionally, AquaNeox contributed to maintaining plasma glucose levels under HD conditions, whereas in control group decreased significantly ($p < 0.05$; Figure 2A). Plasma cholesterol and triglycerides remained stable in fish fed with AquaNeox and reared under HD conditions, showing no significant differences compared to LD group. However, plasma lactate and proteins values decreased significantly in HD group respect to LD group ($p < 0.05$; Figures 2B and 2C), regardless of whether the additive was used or not. Moreover, LD group fed AquaNeox enhanced significantly proteins levels compared to control group ($p < 0.05$; Figures 2C), possibly reflecting a protective effect against oxidative stress.

## Conclusions

The inclusion of AquaNeox modulates hepatic metabolism by reducing hepatocyte cytoplasmic volume and increasing liver triglyceride storage, which is possibly due to altered lipid handling pathways. The additive also helped to maintain plasma glucose levels under HD condition and to increase proteins values under LD condition. Overall, these results suggest a stabilising effect of nutraceutical AquaNeox on energy metabolism. This metabolic adjustment may contribute to improved physiological resilience under intensive farming conditions.

**Introduction**

Intensification of aquaculture practices often involves increasing stocking densities, a strategy that can affect negatively animal welfare. Chronic exposure to crowding stress may lead to metabolic alterations, impaired growth, and immune suppression, ultimately reducing production performance. Functional feed additives with stress-modulating properties are gaining attention as a tool to mitigate physiological impact of intensive farming (Ciji and Akhtar, 2021). This study evaluates the efficacy of a phytogenic additive with calming properties (RELAQUAX, Bedson España S.L.) in the diet of European seabass (*Dicentrarchus labrax*) reared under different stocking density conditions.

**Materials and methods**

A total of four experimental groups were designed in triplicate by combining two diets (control or supplemented with 0.2 % RELAQUAX) and two initial stocking densities: 5 and 25 kg/m$^3$, defined as low density (LD) and high density (HD), respectively. The trial was conducted over three months using *D. labrax* (n = 720; $w_i$ = 29.6 ± 5.9 g) housed in 500 L-tanks, where the density was adjusted by the number of fish and the effective volume of the tank. Fish were maintained under controlled temperature and photoperiod and fed to apparent satiation. Biometric assessments were carried out periodically to determine growth parameters and adjust feeding. At the end of the trial, samples were collected to analyse stress indicators, energy metabolism and hepatocytes' structure.

**Results and discussion**

Including RELAQUAX in the diet did not negatively impact fish growth. Regarding plasma metabolites (see Table 1), control group decreased significantly glucose, lactate and proteins levels under HD conditions. Dietary supplementation with the additive modulated this response, with plasma lactate and proteins levels remaining stable regardless of rearing conditions. The RELAQUAX group enhanced significantly plasma glucose values respect to control group under LD conditions. No significant differences were found in plasma triglyceride or cholesterol levels between the experimental groups. These results suggest that RELAQUAX supports metabolic stability and mitigates the negative effects of stocking stress by maintaining plasma lactate and proteins levels.

The control group increased significantly hepatic cholesterol under HD conditions ($p < 0.05$), with no other significant changes in liver metabolites (see Table 1). Conversely, RELAQUAX supplementation modulated hepatic response, increasing glucose values and decreasing hepatocyte area ($p < 0.05$), while other metabolites remained unchanged. Under LD conditions, RELAQUAX group enhanced significantly triglycerides and cholesterol compared to control group ($p < 0.05$). Under HD conditions, there was a significant increase in liver glucose and a decrease in hepatocyte area relative to control group ($p < 0.05$). These findings suggest that RELAQUAX supports liver metabolic flexibility by modulating glucose and lipid metabolism to maintain energy homeostasis. The decreased hepatocyte area may reflect an adaptive cellular response to stress modulated by the additive (Harper and Wolf, 2009).

**Conclusions**

Supplementing of aquafeed with RELAQUAX maintained plasma lactate and proteins levels under HD conditions, while increasing plasma glucose under LD. In the liver, promoted metabolic adjustments, with higher glucose and lipid levels depending on rearing density, and reduced hepatocyte area, suggesting histological adaptations to stress. Overall, RELAQUAX appears to support metabolic stability and liver flexibility, potentially enhancing physiological resilience under intensive farming conditions.

## Introduction

The growing need to reduce the use of fishmeal and fish oil in aquafeeds has driven interest in sustainable alternatives such as algae, which are rich in essential nutrients and bioactive compounds. However, their high fibre content and rigid cell walls limit digestibility in fish. In order to solve this problem, biotechnological treatments like enzymatic hydrolysis and microbial fermentation help break down structural barriers and enhance nutrient availability (Hua et al., 2019). The golden grey mullet (*Liza aurata*), a euryhaline and omnivorous fish species well adapted to farming, is a promising candidate for aquaculture diversification (Crosetti and Blaber, 2016). This species requires a lower amount of dietary protein during the growth phase, enabling the employ of alternative ingredients and the reduction of production costs. For these reasons, this study assesses the physiological response of *Liza aurata* to bioprocessed algal biomass under feeding and fasting conditions.

## Materials and methods

The algal blend used in this study consisted of 30 % *Arthrospira* sp., 20 % *Chlorella* sp., 10 % *Microchloropsis* sp., 10 % *Tisochrysis* sp., and 30 % *Ulva* sp., provided by LifeBioencapsulation S.L. (Almería, Spain) and stored at -20 ºC until use. The biomass was processed through enzymatic hydrolysis (5h; carbohydrates, cellulase, and proteases), followed by microbial fermentation with *Saccharomyces cerevisiae* and *Bacillus subtilis* ($10^9$ CFU/mL each; 36 h).

A 62-day feeding trial was conducted at the Servicios Centrales de Investigación en Cultivos Marinos (SCI-CM, CASEM, University of Cadiz, Puerto Real, Cádiz, Spain; Facilities for Breeding, Supplying and Users of Experimental Animals; Spanish Operational Code REGA ES11028000312), testing, in triplicate, two experimental diets ($L_{50}$ and $L_{100}$), where 50 % and 100 % of fishmeal and fish oil were replaced by the processed algal product, and a control diet (CT) containing 15 % fishmeal and 5 % fish oil without algal biomass. At the end of the trial, fish growth was assessed. Additionally, the same fish were subjected to a fasting challenge during 9 days to evaluate their metabolic response to nutritional stress. Plasma and liver samples were collected both after the feeding period and following the fasting challenge to analyse metabolic indicators related to energy homeostasis.

## Results and discussion

The partial ($L_{50}$) and total ($L_{100}$) replacement of fishmeal and fish oil with enzymatically pretreated algae biomass had no negative impact on growth, indicating good overall acceptance and utilisation of the diets by the specimens of *L. aurata*. Despite the absence of significant differences in plasma metabolites, there was a trend towards lower plasma glucose, lactate and protein values in the experimental groups. This could indicate lower metabolic stress or improved energy efficiency associated with the use of the algal preparation.

*(Continued on next page)*

Although no significant changes were detected in liver tissue, a trend towards lower glucose concentration and higher glycogen storage in the $L_{50}$ and $L_{100}$ groups was observed, suggesting a more stable energy adaptation in specimens receiving these aquafeeds. Additionally, the $L_{100}$ dietary treatment resulted in a decrease in hepatic triglycerides, potentially reflected an increased use of lipids as an energy source or reduced lipogenesis. Notably, the hepatosomatic index decreased significantly ($p < 0.05$) in the $L_{50}$ group, despite a tendency to enhance hepatic triglyceride content. This apparent contradiction could be explained by a redistribution of hepatic triglyceride content in the $L_{50}$ group.

After the fasting period, no significant differences in biometric parameters were observed between treatments, indicating that the inclusion of the algae preparation did not negatively affect overall body condition following dietary restriction. However, groups that had been pre-fed experimental diets showed a significant reduction in plasma cholesterol ($p < 0.05$). As no differences in this metabolite were recorded during the feeding phase, this decrease suggests a differential metabolic response to fasting with an increased mobilisation of cholesterol (due to the previous dietary treatment). In terms of hepatic metabolites, while no statistically significant differences were detected, the $L_{50}$ group showed a trend towards greater triglyceride and glycogen accumulation, alongside lower glucose concentrations. This response suggests an optimisation of energy reserves, reflecting better metabolic resilience to fasting conditions.

**Conclusions**

Replacing fishmeal and fish oil with enzymatically hydrolysed and fermented algal biomass, either partially or entirely, appears to promote a favourable metabolic profile in *L. aurata* under both fed and fasted conditions. In particular, at intermediate levels of substitution ($L_{50}$), fish enhanced energy storage capacity and presented a more regulated metabolic response during periods of feed deprivation; suggesting an improved physiological resilience without compromising growth or condition.

Nina.Bloecher@sintef.no

Aquaculture uses large amounts of plastic for infrastructure and equipment, which likely contributes to microplastic (MP; <5 mm) release to the environment. In addition to feed pipes and cage collars, pen nets are a potential source for MP release. *In-situ* net cleaning, typically conducted using dedicated pressure washers, may exacerbate abrasion of nets and their coatings, leading to higher MP emissions during cleaning periods. As a result, fibres, as well as synthetic particles from net coatings, may be dispersed into the surrounding seawater.

A laboratory experiment simulating abrasion damage from net cleaning was performed to quantify and compare the relative amounts of MP released from common nylon nets and alternative net materials (HDPE, Dyneema, Entex), applying both new and used net samples. In addition, net samples with two different coatings, used to extend the material lifetime, were included. The abrasion tests were conducted using abrasion equipment from Buraschi, where the nets were subjected to a rotating abrasive drum in a water tank. Particles released into the water were washed and filtered (≥10 µm) before being quantified and physiochemically characterised using a combination of gravimetric measurements, microscope imaging and chemical fingerprinting by pyrolysis GC-MS.

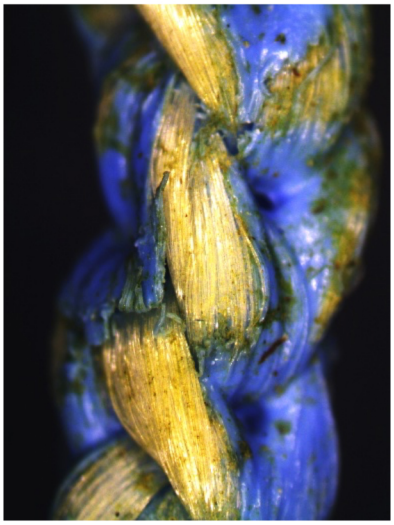

*Figure 1: Nylon net with coating damage after net cleaning*

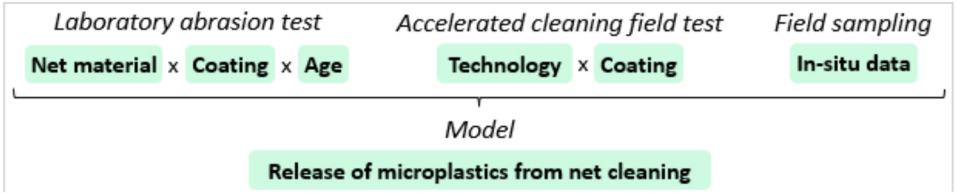

*Figure 2: Overview of the conducted experiments and collected data.*

*(Continued on next page)*

Results indicated higher MP release from the nylon nets compared to the HDPE, Dyneema and Entex nets. Coatings interacted differently with the various net materials, where there was no change in MP release from the coated Dyneema nets, but an increased particle release from the coated nylon nets. Used materials released more MP than new ones.

Based on these results, used nylon nets and new nylon nets with coating were chosen for an accelerated net cleaning test, conducted in full scale at sea. Here, we simulated 10 months of *in-situ* cleaning. Two novel cleaning technologies, cavitation-based cleaning and AUV based brushing, were compared to standard high-pressure based cleaning. The release of MP into the surrounding seawater, as well as abrasion of the coating from nets (Figure 1), were assessed. The MP release was determined using a combination of onsite filtration of seawater during the cleaning processes, and subsequent analysis of the retained particles by μFTIR spectroscopy to determine particle number, size distribution and polymer type.

To validate the results, we also sampled MP from seawater during a set of regular net cleaning events conducted with high-pressure washers at a commercial salmon farm site. Finally, we have modelled release from net cleaning based on the collected data (Figure 2) for different combinations of net materials, coatings, life stages and cleaning technologies to give the aquaculture industry a first indication of which material, coating and cleaning technology combinations may minimise current MP releases to the marine environment. These findings underscore the potential of material selection and maintenance practices in reducing the environmental impact of aquaculture operations.

# EVALUATION OF THE IMPACT OF OXYGENATION SYSTEMS (OXYMAR®) ON HEALTH AND PRODUCTIVE PERFORMANCE IN SALMON FARMING SITES IN CHILE

Gonzalo Boehmwald

OXZO S.A
Km 1012, centro empresarial los volcanes
módulo 16, Puerto Varas, Chile
Josefameneses.al @gmail.com

This study evaluates the impact of OXYMAR® oxygenation systems on the health and productive performance of Atlantic salmon farmed at open-sea sites in Chile between 2021 and 2024. A total of 620 farming centers, operated by 14 companies, were analyzed—comparing those using OXYMAR® technology with those that did not, including a subset affected by mortality associated with hypoxic events.

The primary objective was to determine whether the implementation of OXYMAR® systems improves sanitary and productive outcomes under low-oxygen conditions, thereby contributing to more sustainable aquaculture operations.

The results focus on the performance of sea sites using OXYMAR® in 2024, with geographic distribution across Los Lagos, Aysén, and Magallanes. The use of the technology was associated with a significant reduction in mortality rates (-24%), particularly at sites with frequent monthly oxygen supplementation.

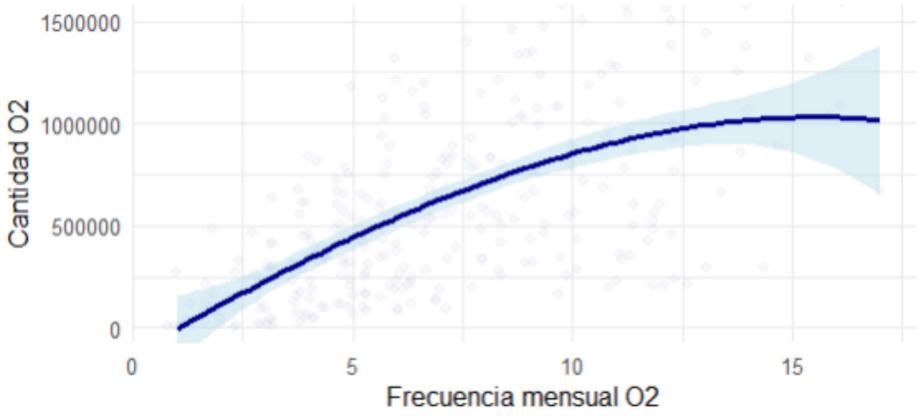

*Figura 6. Gráfico muestra una relación positiva entre la frecuencia mensual y consumo de O2*

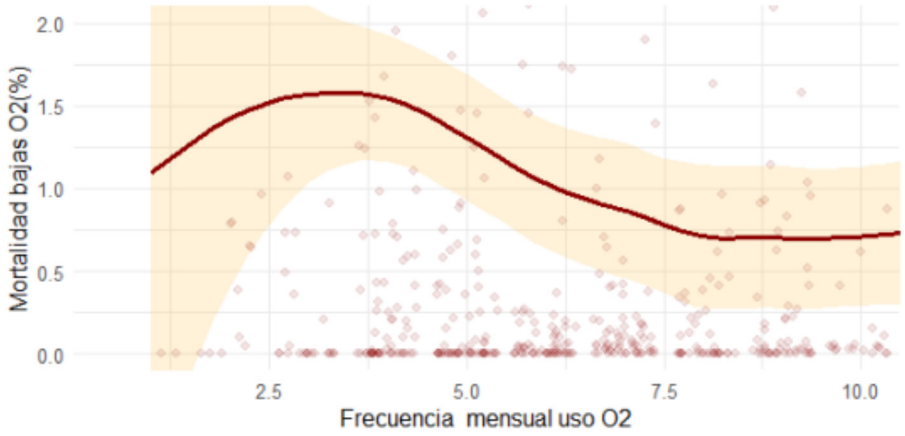

*Figura 7. La mayor frecuencia mensual de consumo se asocia a una menor mortalidad por bajas de oxígeno*

*(Continued on next page)*

Furthermore, sites using OXYMAR® demonstrated improved health indicators, including lower overall mortality and a reduced incidence of infectious diseases such as SRS and BKD. From a production perspective, these sites showed better feed conversion ratios (-2%), shorter production cycles (-5%), and higher specific growth rates (+4%), indicating greater operational efficiency.

These findings underscore the critical role of advanced oxygenation technologies like OXYMAR® in mitigating the effects of hypoxia, enhancing fish welfare, and supporting production stability in increasingly challenging marine environments. The evidence supports the strategic value of integrating oxygenation systems to optimize biological performance, reduce operational risks, and align aquaculture practices with global sustainability goals.

# BROAD-SPECTRUM ANTIVIRAL POTENTIAL OF MARINE INVERTEBRATE EXTRACTS: A BLUE ECONOMY APPROACH

R. Bonet-García[1,*], M. Narváez-Asensio[2], M. Adamek[3], M.L. DeDiego[4], E. Barrajón-Catalán[1], A. Falcó[2]

**Introduction**

Marine ecosystems are a rich source of bioactive compounds, many of which remain largely unexplored. Among marine organisms, invertebrates are particularly notable for their capacity to produce unique secondary metabolites with potential applications (Ruiz-Torres et al. 2019). Viral infections are one of the major challenges to both human health and aquaculture. In aquaculture, viral pathogens cause significant economic losses and threaten the sustainability of fish farming systems, while in human health, effective antiviral treatments remain limited for many viral diseases. This highlights the importance of discovering new antiviral compounds, especially those with broad-spectrum activity and versatility across different sectors (Riccio et al. 2020).

This study investigates the antiviral potential of extracts from four marine invertebrates that target viruses relevant to humans and fish. By exploring the therapeutic potential of marine biodiversity, this research supports the European Blue Economy approach, which is based on sustainably using ocean resources to drive innovation in health and economic development.

**Materials and Methods**

Extracts were prepared from four marine invertebrate species: two nudibranchs (NA and NB), one holothurian (PS) and one soft coral (CR). Organic solvents were used for extraction, and the resulting dry extracts were solubilized in dimethyl sulfoxide. Eight viruses were selected for *in vitro* antiviral screening:

- Human respiratory viruses: human coronavirus (HCoV-229E), human metapneumovirus (hMPV), respiratory syncytial virus (RSV), and influenza A virus (IAV).
- Fish viruses: viral hemorrhagic septicemia virus (VHSV), cyprinid herpesvirus 3 (CyHV-3), tilapia lake virus (TiLV), and common carp paramyxovirus virus (CCPV).

Each viral strain was incubated at virus-specific multiplicities of infection (MOIs) for two hours at the optimal infection temperature. Then, to evaluate antiviral activity, three types of assays were performed: in some cases, viral particles were pre-incubated with the extracts before being added to susceptible cells; in others, cells were pre-treated with the extracts prior to infection. In additional assays, cells were treated throughout the entire infection cycle. Antiviral activity was evaluated by quantifying the percentage of infection inhibition compared to untreated controls for each virus–extract combination.

**Results**

Extracts from NB and NA showed the highest antiviral activity, significantly reducing infection and replication across a broad range of human and fish viruses. These extracts consistently showed greater infection inhibition compared to the other two extracts indicating higher efficacy. Although PS exhibited antiviral activity against certain viruses, it also showed cytotoxic effects at some concentrations, which may limit its applicability.

**Discussion**

The strong antiviral effects of NB and NA extracts suggest the presence of novel and potent bioactive compounds in these two species. These findings are particularly promising for aquaculture, where effective antiviral agents are critically needed. The observed efficacy against human viruses further highlights their potential application in therapeutical development.

*(Continued on next page)*

The design of the trials enables us to formulate very tentative hypotheses about the mechanisms of action. The antiviral effect observed after virus extracts pre-incubation suggests direct virucidal activity, possibly through inactivation of viral particles or interference with their ability to attach to host cells. The pre-treatment of cells suggests a protective cellular effect, such as modulation of viral receptors or activation of cellular defense pathways (Aoki-Utsubo et al. 2018).

Together, these results suggest that NB and NA are promising candidates for the development of broad-spectrum antiviral agents. Further research is, however, required, with the next steps of the investigation focusing on isolating and characterising the active compounds, as well as elucidating their chemical structures and specific molecular targets.

**Conclusion**

This study identifies two marine invertebrates, NB and NA, as promising sources of broad-spectrum antiviral agents. Their demonstrated efficacy against both human and fish viruses highlight their potential for cross-sector therapeutic development, spanning human medicine and aquaculture. Approaches aligned with the Blue Economy, such as the exploration of marine bioactive compounds, will be essential to advancing these findings toward practical, real-world applications. Continued research focused on the isolation, characterization, and mechanism of action of the active compounds will be key to unlocking their full potential.

# COASTAL SPRING WATER ON THE VALENCIAN COMMUNITY COAST (E SPAIN)

D. Bonomo[1]*, J. E. Tent-Manclús[1,2], J. D. Jordá[1,3], M. M. Jordan[4] and J. Navarro Pedreño[4]

[1] Multidisciplinary Institute for Environmental Studies "Ramón Margalef", Alicante University, 03690-San Vicente del Raspeig, Alicante, Spain

[4] Dpt. of de Agrochemistry and Environmental Science, University Miguel Hernández, 03202-Elche, Alicante, Spain

**Introduction**

Coastal aquifers of the Valencian Community are currently heavily overexploited. Some freshwater springs, such as Peñiscola, are still recognized, indicating the existence of others that currently do not discharge into the sea but into a coastal freshwater lagoon, such as the Albufera de Valencia, or others that are only active during rainy periods, such as Toix (Tent-Manclús et al., in press).

**Discussion**

In the 17th century, Gaspar Escolano (1611) made a description of the coasts of the Kingdom of Valencia, described different sources of fresh water along the coast. In Peñiscola (Province of Castellon), a water spring near where the waves break became salinized and then returned to be fresh water, being one of the first documented mentions of natural coastal salinization and its reversal. The Albufera of Valencia was a lagoon of sea water connected to the sea that had freshwater springs, used by fishermen. Today, some springs called "ullals" are still active and already pour into a coastal lagoon of fresh water instead. The change was produced by the human activity at the end of the 18th century (Sanchis Ibor, 2010).

Finally, in Alicante, he mentions the Agua Dulce cove in Denia and the sandbank of Rio Seco. Special mention has to the description of the important coastal spring of the Morro de Toix seacliff, now mainly inactive most of the year around and only active after major rain episodes as the one on March 26th, 2025 were the under sea-level springs worked as can see in the Figure 1. The Escolano's description of Morro de Toix mentioned that the big current produced by the spring did not allow the small boats to get closer to it. Also, Cavanilles (1797) describe as active coastal spring.

**Conclusion**

The ancient coastal spring water of the Valencian Community of 400 years ago from historical sources had been revised. Most of the springs are not discharging due to the great anthropic modification of the 20th-21st centuries.

**Introduction**

One of the major limitations of traditional bathymetric and Side Scan Surveys are the shallow waters, less than 5 m depth, where the campaign ships have poor maneuverability, and the waves are increased. Unmanned or Uncrewed Surface Vessels (USV) are remote controlled vehicles or autonomous vehicles that can work in shallow depth areas, narrow channels, and hazardous areas. They are the best option for shallow waters if the marine weather conditions are appropriate, as low waves and almost non-tide currents.

Our group of the University of Alicante has developed a low-cost USV platform to be used in coastal, rivers and lake studies (Ronda et al, 2023; Benabdeloued et al., 2025). The main advantage is an affordable and easily adaptable USV, not dependent on external developers, and changeable on-demand.

**USV description**

The USV is based on an Arduino mainboard to control the Electronic Speed Control (ESC) of the thrusters, the GPS and the antennas for sending signals and two video-cameras, one underwater, facing down, and other above the water, facing to the front. The ship was designed to be easily transported and operated in areas with limited access, such as densely vegetated lake margins, as the thruster are protected by a steel net. It can be equipped with various sensors, during different development phases a Furuno single-beam was used, and at the moment is updated with a Lowrance Elite FS 3-in-1 single-beam, down-scan and side-scan sonar with an own GPS plotter (Benabdeloued et al., 2024).

To test the platform, it was deployed in different study sites: as spring ponds (Ronda et al., 2023), and the sea-cliff (Bonomo et al., 2025). For this last one, the side-scan sonar equipped USV provided detailed seabed sonar images and lateral underwater vertical sea-cliff, uncovering the underwater excavation of the cliff and the nearby seabed with karstic features such as caves and blocky bottom. The system shows the effectiveness in collecting high-resolution bathymetric data, even in challenging environments.

**Discussion and conclusion**

The key advantage of the system lies in its low cost, adaptability, and the ability to collect data in areas that would otherwise require expensive equipment. This research highlights the potential of USVs for advancing aquatic and coastal studies, offering a scalable solution for both academic and applied environmental research. Our system is in a continuous development, as in the near future will be updated with new sonar transducers.

# CLONING AND CHARACTERIZATION OF A *VASA* HOMOLOG IN THE GIANT GROUPER (*Epinephelus lanceolatus*) AND ITS SPECIFICALLY EXPRESSION IN GONAD

S. Boonanuntanasarn[1], O. Mengyu[2], S. Detsathit[2] and A. Jangprai[1]

[1]School of Animal Technology and Innovation, Institute of Agricultural Technology, Suranaree University of Technology, 111 University Avenue, Muang, Nakhon Ratchasima 30000, Thailand
[2]Krabi Coastal Fisheries Research and Development Center, 141 Moo 6, Saithai, Muang, Krabi 81000, Thailand
Email: surinton@sut.ac.th

The *vasa* gene has been the most commonly used gene marker for germ cells in vertebrates, particularly in fish. This study aimed to clone and characterize a *vasa* homolog in the giant grouper (*Epinephelus lanceolatus*), which was designated as *Elvasa*. Our results showed that *Elvasa* contained predicted regions sharing consensus motifs with the *vasa* family in teleosts, including arginine-glycine (RG) repeats, arginine-glycine-glycine (RGG) repeats, ATPase motifs, and a DEAD box. Phylogenetic tree analysis showed that *Elvasa* was located on a branch of the *vasa* family tree and was clearly distinct from PL-10. Reverse transcription PCR was performed to determine the tissue distribution of *Elvasa*. Our results showed that, using cDNA preparations from the heart, liver, spleen, intestine, kidney, muscle, and gonads (ovary and intersex), *Elvasa* transcripts were detected only in the gonads. Histological examination and *in situ* hybridization were performed on the ovary, and the results showed strong positive signals for *Elvasa* in primary oocytes. Therefore, *Elvasa* showed specifically expressed in gonad, which could be used for germ cell marker. Therefore, Elvasa was specifically expressed in the gonads and could be used as a germ cell marker.

# INNOVATIVE SUSTAINABLE AQUACULTURE PRACTICES: SALMON AND MICROALGAE LAND-BASED IMTA

H. Böpple[1*], P. Steinrücken[1], M. Andrews[2], P.M. Slegers[3], Dorinde M.M. Kleinegris[1,4]

[1] NORCE Norwegian Research Centre, Bergen, Norway
[2] Marineholmen RASlab, Bergen, Norway

E-mail: habp@norceresearch.no

## Introduction

The Farm-to-Fork Strategy of the European Green Deal acknowledges the potential of algae to become an important source of alternative low-carbon footprint protein and contribute to improving the sustainability and competitiveness of the aquaculture sector (Gallego et al., 2025). Within this context, we have developed and demonstrated the integration of fish and algae cultivation in coupled, land-based RAS/IMTA (Recirculating Aquaculture Systems/ Integrated MultiTrophic Aquaculture) systems. This concept aims to minimize energy and nutrient losses and maximise resource efficiency by closing the nutrient loop.

## Material and Methods

In the land-based RAS/IMTA for salmon production connected to microalgae cultivation, we studied the nutrient uptake and microalgae biomass productivity on the RAS effluent water. The nitrogen and phosphorous concentrations of the RAS effluent water change over time and are highly dependent on the operation conditions of the production systems. Moreover, the nutrient concentrations are generally lower than the concentrations used for fertilization at industrial scale microalgae production. Therefore, we explored the possibility of microalgae cultivation systems adaptable to different hydraulic retention times for the water and the algae, i.e. a biofilm reactor and a perfusion system. Perfusion cultivation was tested through the integration of a membrane filtration system. The performance was compared to continuous cultivation with and without additional fertilization. The microalgae species *Chlorella vulgaris* and *Phaeodactylum tricornutum* were used for the freshwater experiments and brackish/seawater experiments respectively.

Furthermore, a life cycle assessment was conducted to evaluate the potential environmental impacts for the different microalgae cultivation methods. A preliminary economic evaluation used to determine the differences in capital expenses and operational expenses between the two microalgae cultivation modes.

## Results and Discussion

We successfully demonstrated nutrient remediation for RAS effluent water, during the freshwater, brackish water and seawater stages of the salmon production, for both microalgae species *Chlorella* and *Phaeodactylum*. Results showed that high microalgae productivities could be achieved (up to 2.15 g $L^{1}$ $d^{-1}$), as well as high nutrient uptake rates (up to 1888 mg $NO_3$ $L^{-1}$ $d^{-1}$ and up to 252 mg $PO_4$ $L^{-1}$ $d^{-1}$). A steady state microalgae cultivation with stable optical densities and dry weights cultivation was obtained for all experiments. The results from the lab experiments were used to update and expand an existing model for 1 ha microalgae cultivation (Böpple et al., 2025; Vázquez-Romero et al., 2022). A life cycle assessment (LCA) and preliminary economic assessment of the upscaled model showed that perfusion cultivation appears to have a lower environmental impact for treating RAS effluent water with low nutrient concentrations, but leads to increased operational (6 %) and capital expenses (up to 60 %) due to additional equipment and energy demands. The infrastructure of the photobioreactor and the electricity needed during cultivation contribute the most to the environmental impacts.

Although the potential application of microalgae in aquaculture feed could improve the sustainability of fish feed (Ansari et al., 2021), a clearer regulatory framework is needed regarding microalgae cultivated on ‘waste streams’ from aquaculture for food and feed production.

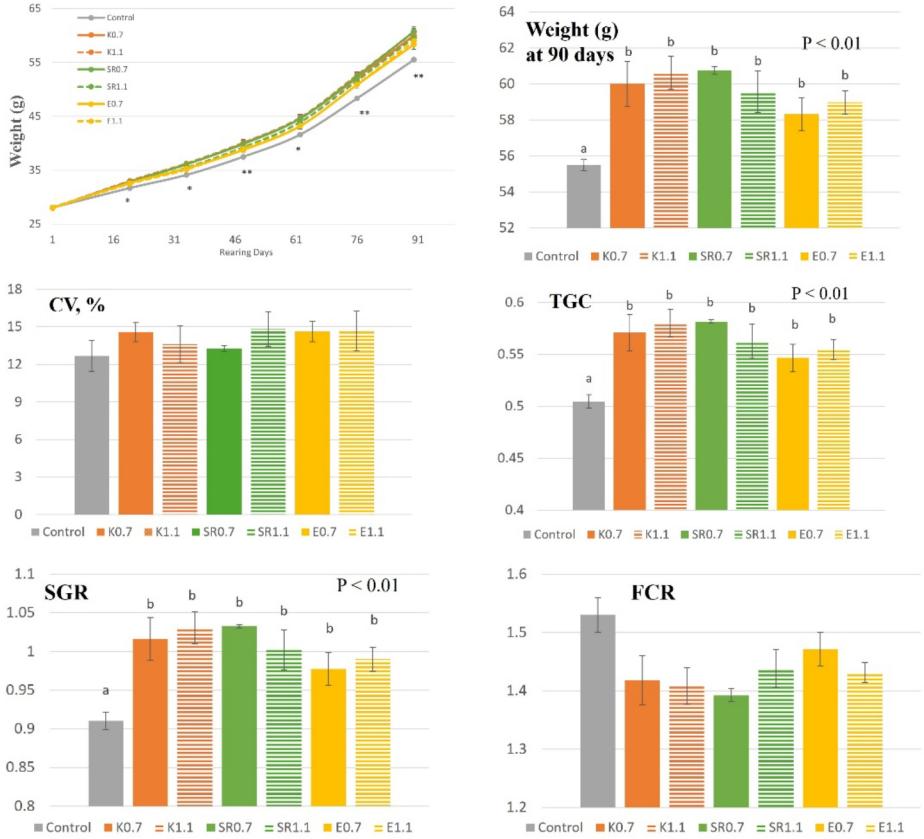

Figure 1: Growth performance of gilthead seabream after 90 days of rearing.

# PARTIAL REPLACEMENT OF FISH MEAL WITH HYDROLYSED FEATHER MEAL IN THE DIET OF GIANT RIVER PRAWN (*Macrobrachium rosenbergii*) DURING THE NURSERY PHASE

F. Bordignon*, C.H. do Nascimento Ferreira, M. T. Mauerwerk, M. C. Retcheski, H. Cazarolli, A. Trocino, and E. L. Cupertino Ballester

Department of Agronomy, Food, Natural resources, Animals and Environment (DAFNAE)
University of Padova, Italy
E-mail: francesco.bordignon@unipd.it

## Introduction

Freshwater species like the giant river prawn (*Macrobrachium rosenbergii*) are a promising alternative to other farmed crustaceans due to their high market value and significant production, which reached 294,000 tons in 2020 (2.6% of total crustacean farming) (FAO, 2022). However, optimizing their nutrition remains a challenge, particularly in identifying sustainable protein sources.

Among the alternatives to fish meal, hydrolysed proteins from processed animal by-products (PAPs) such as hydrolysed feather meal (HFM) could offer a viable solution, improving feed efficiency while reducing waste. Despite their potential, research on the use of PAPs in freshwater prawn diets, particularly during early developmental stages like post larvae, is still limited.

This study evaluates the effects of HFM inclusion in *M. rosenbergii* post larvae diets, assessing growth performance, digestive enzyme activity, antioxidant status, and whole-body composition.

## Material and Methods

A total of 1600 *M. rosenbergii* postlarvae (0.021 ± 0.006 g) were distributed into 20 aerated 250-L tanks, each connected to a recirculating system with a Bead filter (1200 L $h^{-1}$ flow rate). Prawns were randomly assigned to five diets with different HFM inclusion levels (0.0%, 1.5%, 3.0%, 4.5%, 6.0%) and four replicates per diet. Diets were formulated to be isonitrogenous (44.2 ± 0.4% crude protein) and isolipidic (14.8 ± 0.1% crude lipids). Ingredients were ground (0.5 mm sieve), mixed, pelleted, and feeds stored at 4 °C until use. A 32-day feeding trial was run, which included five daily feedings (9:00, 11:00, 14:00, 17:00, 21:00). Tanks were siphoned before the first feeding to remove faeces and uneaten food. The initial feeding rate (10% of biomass) was daily adjusted daily based on consumption. Mortality was recorded twice daily. A 12 h light/12 h dark photoperiod was maintained. Temperature and dissolved oxygen were measured daily; total ammonia nitrogen and nitrite, three times a week; hardness and alkalinity, biweekly. Water parameters were within the recommended range for *M. rosenbergii* farming (mean ± SD): temperature 29.35 ± 0.91 °C, dissolved oxygen 6.10 ± 1.05 mg $L^{-1}$, pH 8.34 ± 0.09, hardness 108 ± 19 mg $CaCO_3$ $L^{-1}$, alkalinity 107 ± 11 mg $CaCO_3$ $L^{-1}$, total ammonia nitrogen 0.011 ± 0.015 mg $L^{-1}$, and nitrite 0.003 ± 0.29 mg $L^{-1}$. At the end of the trial, survival, final weight, length, antenna length, biomass gain, and feed conversion rate were assessed. Hepatopancreases from 100 prawns (20 per diet) were collected to analyse digestive enzyme activity, antioxidant activity, and lipid peroxidation. Data were tested for homogeneity (Levene's test) and normality (Shapiro–Wilk's test). One-way ANOVA followed by Tukey's test was used for analysis. Results are expressed as mean ± SEM, with $p<0.05$ considered statistically significant.

## Results and discussion

Survival rates ranged from 73.3±5.4 % to 83.3±3.8 % without significant differences among treatments ($p>0.05$). All treatments with HFM inclusion showed significant higher final weight in comparison with the control treatment ($p<0.05$). Final weight, final length, and biomass gain were significantly higher in prawns fed diets with 6.0% HFM ($p<0.05$) and the feed conversion rate was significantly improved by the same diet ($p<0.05$). Additionally, prawns fed diets containing 4.5% or 6.0% HFM inclusion had significantly longer antennae ($p<0.05$), suggesting improved welfare conditions (Furtado et al., 2015).

Antioxidant status did not change according to the dietary treatment ($p>0.05$), suggesting that HFM did not induce oxidative stress or disrupt prawn redox balance. In details, thiobarbituric acid reactive substances (TBARS) averaged 0.94 ± 0.13 µM/mg protein; reduced glutathione (GSH) 1.70 ± 0.37 µM/mg protein; glutathione S-transferase (GST) 0.18 ± 0.04 nMol tioeter/min/mg protein; glutathione peroxidase (GPx) 0.88 ± 0.16 µM NADPH/min/ mg protein; and glutathione reductase (GR) 0.73 ± 0.18 µM NADPH/min/mg protein.

*(Continued on next page)*

The lack of differences in digestive enzyme activity according to the diet suggests that HFM inclusion of up to 6% did not significantly alter the digestive physiology of prawns post larvae, both at carbohydrate (maltase: 11341 ± 2902 U/mg protein, on average; sucrase: 4266 ± 1233 U/mg protein) and protein (chymotrypsin: 4.94 ± 0.73 µmol/min/mg protein; trypsin: 1.54 ± 0.25 nmol/min/mg protein) digestion level. On the other hand, in Pacific white shrimp (*Penaeus vannamei*) fed 6% of HMF during the grow-out phase, higher levels of trypsin activity were recorded compared with the control diet, suggesting a potentially enhanced protein digestion (Negrini et al., 2024a), while no changes were observed in Pacific white shrimp fed similar diets during the nursery phase (Negrini et al., 2024b).

**Conclusions**

Hydrolysed feather meal inclusion up to 6% improved growth performance, feed conversion, and welfare in giant freshwater prawns without compromising digestive enzyme activity or antioxidant status. These findings suggest that HFM is a viable alternative protein source that supports efficient digestion and shrimp health. Additionally, its use promotes circularity also in crustacean aquaculture by valorising poultry by-products, reducing reliance on traditional protein sources, and enhancing the sustainability of prawn production.

# NUTRITIONAL INTERACTIONS BETWEEN ZINC AND OMEGA-3 FATTY ACIDS: IMPACTS ON SKIN REPAIR AND SKELETAL DEVELOPMENT IN ATLANTIC SALMON

M. Bou[1]*, E. Ytteborg[1], G. M. Berge[2], L. Sveen[1], E. Lutfi[1], A. Krasnov[1], T-K. Østbye[1], G. Timmerhaus[1], and B. Ruyter[1]

Marta.bou@nofima.no

**Introduction**
The growth of the salmonid aquaculture industry has driven major changes in feed composition, leading to diets with higher lipid content and increased use of plant-based ingredients. As a result, these diets often contain reduced levels of the omega-3 fatty acids EPA and DHA. Additionally, due to environmental concerns and regulatory restrictions, zinc (Zn) content in salmon diets has also been reduced. The aim of this study was to investigate the interactions between dietary Zn and omega-3 fatty acids in relation to growth, body composition, skin health, and bone development in Atlantic salmon, using a combination of *in vivo* and *in vitro* approaches.

**Material and Methods**
Atlantic salmon parr (initial weight: 5 g) were fed six experimental diets for five weeks in triplicate tanks. These diets varied in Zn (120, 180, and 220 mg/kg, referred to as low [LZn], medium [MZn], and high [HZn], respectively) and EPA+DHA content (1% or 3%, referred to as low [LΩ] or high [HΩ], respectively). At the end of the feeding trial, skin and vertebra samples were collected from 10 fish per tank, flash-frozen in liquid nitrogen for chemical analyses, and fixed in 10% formalin for histological analysis. An additional 10 fish per tank were frozen at −20°C for whole-body fat analysis, fatty acid composition, mineral content, and vertebral X-ray and CT imaging.

To assess wound healing, 36 fish from each dietary group were transferred to a common tank and continued on their respective experimental diets for a 6-week wound healing trial. Two standardized skin wounds were inflicted: a superficial wound created by brushing five times with a toothbrush horizontally, and a deep wound involving a vertical incision approximately 2 mm long and 2 mm deep. Tissue samples from the wound areas were collected at 4 days and 6 weeks post-wounding for gene expression and histological analysis.

Three *in vitro* experiments were also conducted, using scales collected from six fish. Five scales per fish were placed in each well, totalling 30 scales per treatment, tested in triplicate. Four conditions were evaluated: control, 0.5 mg/L Zn, 10 µM DHA, and a combination of 0.5 mg/L Zn + 10 µM DHA. The effect on cell migration was measured as the ratio of scales with migrating keratocytes to those without.

**Results and discussion**
The experimental diets had no significant effects on growth performance, as measured by standard growth rate (SGR) and thermal growth coefficient (TGC). As expected, the dietary content of EPA+DHA was reflected in whole-body fatty acid composition, and Zn concentrations in the whole body, skin, and vertebrae increased proportionally with dietary Zn levels. Interestingly, a synergistic effect between Zn and EPA+DHA was observed, particularly at the highest inclusion levels (3% EPA+DHA and 220 mg/kg Zn), resulting in elevated tissue Zn concentrations. Fish receiving this diet also exhibited the highest bone density. Analysis of scale maturation in the skin showed that fish fed the lowest Zn levels (HΩ/LZn and LΩ/LZn) had the least mature scales, while those fed high Zn and high omega-3 (HΩ/HZn) had the most mature scales by the end of the trial. Spinal deformities were observed in 6% of the fish, with twice as many deformities occurring in the LZn groups compared to those fed MZn or HZn, regardless of EPA+DHA content.

Wound healing assessments of mechanically induced injuries (deep cut, superficial wound, and surrounding skin) showed faster scale regeneration in fish fed diets containing the highest levels of both Zn and omega-3. Additionally, the *in vitro* model using salmon scales demonstrated that Zn and DHA both enhanced the migratory capacity of keratocytes. Since rapid keratocyte migration and scale regeneration are critical for wound healing and maintaining skin integrity, these findings underscore the role of these nutrients in fish health.

**Conclusion**
Overall, this study highlights the importance of balancing dietary Zn and omega-3 fatty acids to support optimal growth, skin and bone development, and overall welfare in Atlantic salmon.

# INCREASED DIETARY PHOSPHOLIPISDS OF MARINE OR PLANT ORIGIN, BUT NOT OF ANIMAL ORIGIN, ENHANCE GROWTH PERFORMANCE OF JUVENILE GILTHEAD SEABREAM *Sparus aurata*

## Introduction

It is already widely accepted that fish larvae need high levels of phospholipids (PLs) in their nutrition to ensure optimal growth. Phospholipids are important structural components of cellular membranes, and during the larval stage the formation of tissues and organs is still underway (Sargent et al. 2002; Saleh et al. 2012). On the other hand, there is no solid data regarding phospholipid needs of fish in the juvenile stage or later. This may be because there is some evidence, albeit limited, of the existence of a phospholipid biosynthesis mechanism in fish (Sargent et al. 2002). Currently in Mediterranean aquaculture genetic selection programs are in place that have achieved improved growth rates in fish (Ferosekhan et al. 2022). Knowing that faster weight gain also means faster tissue growth, questions are raised about whether the current nutritional design of feeds are adequately covering the needs of fish in structural nutrients, such as phospholipids. The aim of the present study is to investigate if the increased nutritional intake of PLs will affect production and physiological characteristics of gilthead seabream juveniles (*Sparus aurata*). Simultaneously, different PL sources will be explored (marine, plant, animal) regarding their efficiency.

## Materials and methods

Seven different diets (treatments) were formulated and produced, of which one was used as a Control diet (typical composition of commercial diets, PL 0.5%). The rest of the diets contained, in pairs, different phospholipid sources (krill-K, soy/rapeseed-SR, egg-E) in two levels (PL 0.7% and PL 1.1%). Going forward the diets will be referenced to as K0.7 and K1.1, SR0.7 and SR1.1 and E0.7 and E1.1. Twenty-one homogeneous groups of 20 juvenile gilthead seabream with initial body weight (BW) 28.0 ± 0.13 g (triplicated groups for each treatment) were used. Fish are fed a restricted ration according to water temperature and BW. Mean water temperature is 17.3 ± 0.7 $^{o}$C. When the fish have tripled their initial weight, the trial will end, and they will be weighed and sampled. The growth parameters that are being investigated include: fish weight (W) and its coefficient of variation ($CV_w$), specific growth rate (SGR), feed conversion rate (FCR) and thermal growth coefficient (TGC). For TGC, degree days (DDs) are also calculated (1538.25 for 90 days of rearing). Additionally, the physiological condition of the fish will be evaluated by analyzing blood samples (cholesterol, glucose, albumin, triglycerides, total protein). The trial is ongoing, therefore the results presented below concern the growth for the first 90 days of the experimental rearing.

## Results and Discussion

Fish weight was significantly lower in the Control diet after 90 days of rearing, regardless of the phospholipid inclusion level and origin (Figure 1). This was already observed only two weeks after the beginning of the trial. No differences were observed for $CV_w$ and FCR among diets. SGR and TGC for all experimental diets were equally significantly higher than Control diet (Figure 1). The results for the first 90 days of rearing suggest that gilthead seabream juveniles have higher phospholipid needs than previously reported. It is also encouraging that despite low water temperatures, there is still an obvious improvement in growth. Regarding the efficiency of the different origins of PLs, the present absence of differences does not permit a conclusive evaluation yet. However, it seems that the inclusion of egg PLs doesn't seem to be as efficient as the inclusion of marine and plant PLs. The limited literature data does not permit adequate comparisons with present results, especially when most studies focus on increasing the phospholipid levels of feeds that have a very low fish meal percentage. However, present results suggest that gilthead seabream juvenile growth is affected by the level of dietary phospholipids and indicate a differential effect of PL origin.

Aquaponics is an innovative food production technique, deriving from the integration of recirculating aquaculture system (RAS) and hydroponics, suitable for development of urban and peri-urban food productions[1,2]especially in Europe. Whilst aquaponics broadly combines recirculating fish culture with hydroponic plant production, the application of the term aquaponic is broad and many technologies claim use of the name. Combining fish culture with aquatic-based, terrestrial plant culture via aquaponics may be better defined via its nutrient resource sharing credentials. Aquaponics applies several principles including, but not limited to, efficient water use, efficient nutrient use, lowered or negated environmental impact and the application of biological and ecological approaches to agricultural fish and plant production. Water sources are important so that the nutrients required for fish and plant production are available and balanced, and system water chemistry is paramount to optimised fish and plant production. Systems may be configured in several ways, including those that are fully recirculating and those that are decoupled. Aquaponics importantly seeks to apply methods that provide technical, biological, chemical, environmental and economic advantages.",",container-title":"Aquaponics Food Production Systems",",event-place":"Cham",",ISBN":"978-3-030-15942-9",",language":"en",",note":"DOI: 10.1007/978-3-030-15943-6_5",",page":"113-143",",publisher":"Springer International Publishing",",publisher-place":"Cham",",source":"DOI.org (Crossref. However, high CAPEX/OPEX of aquaponics require a careful selection of highly remunerative products in order to achieve economic sustainability. Aquaponics practiced in brackishwater conditions seems to offer interesting options for sectorial diversification.

The present work, performed in the framework of the Interreg Italy-Slovenia project BEBLUE, aims at studying the functioning of a pilot aquaponic farm rearing gilthead seabream (*Sparus aurata*), in combination with macroalgae (*Ulva rigida*) and samphire (*Salicornia europea*). The approach was based on the precision fish farming framework[3], combining monitoring efforts with the development of a digital twin of the aquaponic farm. The digital twin is a dynamic mathematical model describing the evolution of the aquaponic system, through the simulation of: 1) the key metabolic processes of fish, primary producers and bacteria; 2) the water balance and the transport process of the suspended solids and the dissolved metabolites; 3) the chemical equilibria regulating solution acidity. The model includes four typical components of an aquaponics system, namely: 1) Fish Tank (FT); 2) Mechanical Filter (MF); Biofilter (BF) amd GreenHouse.

The model was tested by comparing its outputs with the experimental data gathered by monitoring the pilot system over a 4 months period, between April 15$^{th}$ and August 15$^{th}$ 2024. Model results (Figure 1) successfully reproduced the observed seabream and samphire individual weight and total biomass, as well as the concentration of the abiotica variables: Dissolved Oxygen and Total Ammonia Nitrogen are shown in Fig. 1. Simulated and observed nitrate concentration, not shown, presented in increasing trend, highlighting that the cultivated crop surface could assimilate only a small fraction of the N metabolized by the fish. This output can be of interest for system design, supporting a correct dimensioning. Observed fluctuations in oxygen concentration were reproduced satisfactorily, showing a slightly lower $O_2$ concentration in the biofilter, although compensated by an adequate reaeration rate. Also in this case, the model could be of help for dimensioning the air insufflation systems and producing early warning of oxygen drifts. The three variables defining the carbonate system, total alkalinity, DIC, and pH, are correctly represented, with a slight underestimation of pH during the initial phase of the simulation. The capability of simulating the carbonate system dynamics is useful for an informed optimization of pH conditions which are contextually adequate for the biofilter and the crops.

Modelling and monitoring results were discussed, to derive a set of recommendations for the development of aquaponics in brackish water.

Allocated Zones for Aquaculture (AZA) represent a strategic tool for the sustainable development of the sector in the Mediterranean Sea (Macias et al., 2019). AZA identification and planning, currently being carried out throughout the basin, are facing relevant challenges, such as coexistence with conservation priorities and existing maritime activities, as well as climate resilience. In this framework, the use of freely accessible geospatial data represents a strategic asset.

The present contribution focuses on a case study of AZA planning, reviewing how mathematical modelling and geostatistical analysis supported data processing and informed planning choices. The case study was carried out within the AZA-RER project (PN FEAMPA 2021-2027), considering the Emilia-Romagna region, the most important Italian region in terms of shellfish production (*Mytilus galloprovincialis, Ruditapes phylippinarum*, *Crassostrea gigas*). Data sources were Copernicus Marine Service (CMS) and European Marine Observation and Data NETwork (EMODNET), complemented by data on operational oceanography made available by the local Environment Protection Agency (ARPAE). Open data exploitation by means of different mathematical and statistical models were compared, carrying out an analysis of the spatial maps produced, and identifying the existing knowledge gaps. Future developments are discussed, in relation to the application of the proposed data exploitation framework for participatory mapping within the ongoing stakeholder engagement process.

## Introduction

Slaughter is a major welfare concern in aquaculture, with an estimated 78–171 billion fish killed annually. Humane slaughter methods must ensure fish are rendered insensible—unable to perceive or respond to stimuli—prior to death and remain so without experiencing fear, pain, or distress. While electroencephalography (EEG) based neurophysiological indicators are the gold standard for assessing sensibility, their use requires specialist equipment and expertise, limiting feasibility in commercial settings.

As a result, operational indicators—such as the loss or recovery of equilibrium, ventilation, and the 'eye-roll' reflex—are commonly used on farms to assess sensibility. However, concerns remain regarding the time lag between these indicators and the actual cessation or recovery of brain activity. Additionally, these indicators may signify immobilization rather than true insensibility. Misjudging sensibility can compromise animal welfare during procedures such as exsanguination or evisceration.

To ensure their reliability, operational indicators must be validated against neurophysiological benchmarks on a species- and method-specific basis. Yet such validation is lacking for European seabass (*Dicentrarchus labrax*) and gilthead seabream (*Sparus aurata*). This study addresses that gap by comparing operational and neurophysiological indicators during gradual (anaesthesia immersion) and rapid ('in-water' electrical stunning) transitions into and out of insensibility in both species, assessing the extent to which operational indicators reliably reflect true insensibility.

## Materials and methods

*Loss of indicators during gradual induction into insensibility*

To evaluate the gradual induction into insensibility in seabass (n = 16) and seabream (n = 14), fish were transferred to a container containing saltwater with an anaesthetic solution (salinity = 9.2 ‰, temperature = 24.0ºC, anaesthetic = 600 ppm 2-phenoxyethanol). Operational indicators (*e.g.*, loss of equilibrium, ventilation, and 'eye-roll' reflexes) and the loss of VERs were then monitored during the gradual induction into insensibility.

*Recovery of indicators following acute induction into insensibility*

To evaluate the recovery of seabass (n = 21) and seabream (n = 27) following acute induction into insensibility, fish were transferred to a darkened, in-water electrical stunning chamber containing saltwater (salinity = 9.2 ‰, temperature = 23.8ºC). Fish were then individually subjected to a 30 s electrical stun (*i.e.*, 50 Hz AC, current density of 3.04 A $dm^{-2}$, electrical field strength of 1.68 V $cm^{-1}$) and the recovery of operational indicators and VERs were then monitored

## Results and discussion

Until neurophysiological monitoring becomes feasible in commercial practice, detailed, species- and method-specific validations of operational indicators remain essential. This study highlights the limitations of operational indicators and underscores the critical need for robust, context-dependent assessments to safeguard fish welfare during slaughter in aquaculture.

*(Continued on next page)*

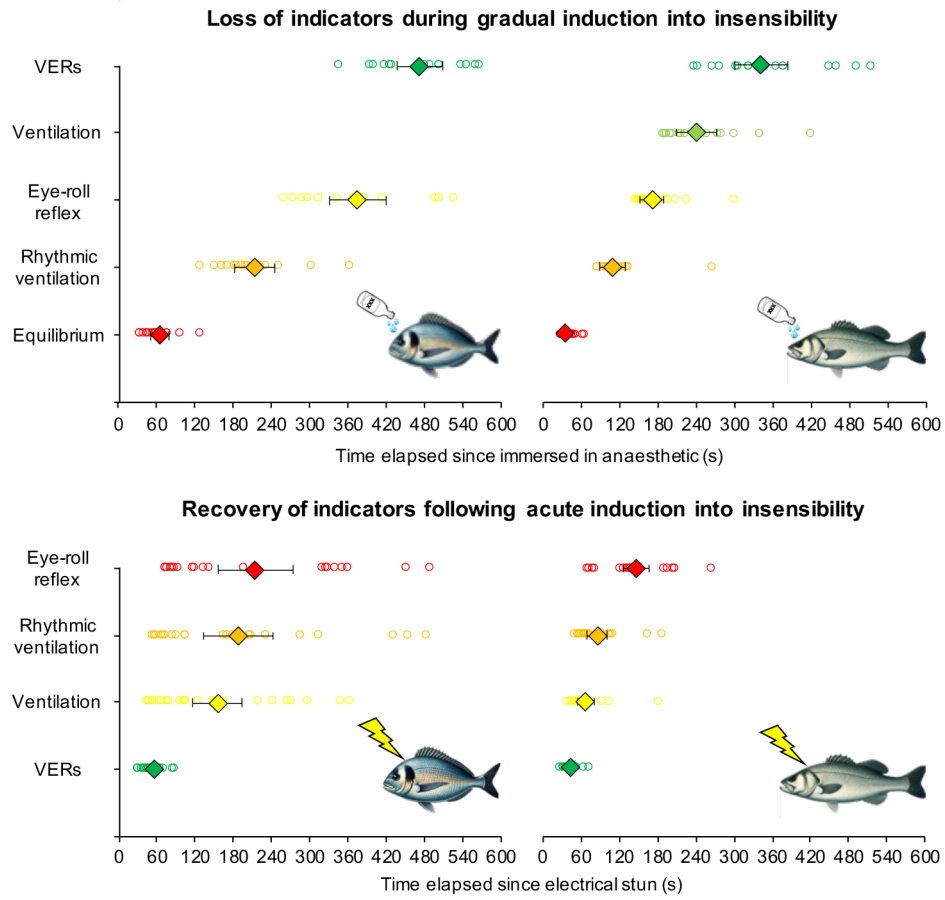

**Figure 1:** The relationship between operational and neurophysiological indicators during a gradual, or following an acute, induction into insensibility in seabass and seabream. Raw data points are represented by the unfilled coloured circles, while the mean ± 95% C.I. are represented by the filled coloured diamonds and error bars.

Our findings reveal significant temporal mismatches between operational and neurophysiological indicators of sensibility. During anaesthetic immersion, all operational indicators were consistently lost before VERs, with equilibrium lost first and ventilation last (see upper panel of Fig. 1). This mismatch ranged from 1.3 to 8.1 times faster than VER loss, depending on the indicator and species. Similarly, following electrical stunning, operational indicators reappeared substantially later than VERs, by factors ranging from 1.4 to 4.7 (see lower panel of Fig. 1). These findings confirm that an exclusive focus on the absence of operational indicators may lead to incorrect assumptions about the neural state of the individual. Clear interspecies differences also emerged. Seabass lost and regained sensibility faster than seabream across nearly all indicators. Interestingly, the sequence of indicator loss differed between species during anaesthesia, further supporting the need for species-specific welfare assessments.

Despite the rising use of electrical stunning, the majority of fish regained VERs within seconds to minutes following a 30 s ‘in-water’ electrical stun. In fact, more than half of individuals already displayed VERs by the time EEG recordings began, underlining how quickly sensibility can return. This rapid recovery poses a serious welfare hazard if not followed by prompt and effective killing. Consequently, there is an urgent need to rigorously evaluate, improve, and validate electrical stunning methods in seabass and seabream before promoting and implementing them as ‘humane’ stunning methods.

# EFFECTS OF DIETARY SOLUBILIZED MANNANOLIGOSACCHARIDES ON PERFORMANCE *Penaeus vannamei*, RAISED IN AN INTENSIVE SYNBIOTIC SYSTEM

Danielle Alves da Silva[a], Suzianny Maria Bezerra Cabral da Silva[a], João Fernando Albers Koch[b], Luis Otavio Brito da Silva[a*]

[a]Universidade Federal Rural de Pernambuco, Brazil
[b]Biorigin Brazil
Email: luis.obsilva@ufrpe.br

## Introduction

A new generation of MOS-based prebiotics is emerging that achieves solubilization of the mannan layer within the yeast cell wall, making it more accessible and partially exposing the glucan layer. This synergistic process enhances the overall efficacy of these prebiotics. β-Glucan is a complex polysaccharide that has been shown to have remarkable immunostimulatory, anti-inflammatory and antioxidant properties in aquatic animals. This study was conducted to evaluate the effects of dietary supplementation with commercially available solubilized mannanoligosaccharides (MOS) on performance, health status (gut bacterial and fungal counts, ammonia and nitrite stress, gut morphology), and economic benefits of Pacific white shrimp, *Penaeus vannamei* raised in an intensive synbiotic system.

## Material and methods

This diet was designed to be both isoproteic (360 g of protein per kg) and isoenergetic (4400 Kcal per kg). The commercial source of mannan oligosaccharides (MOS) used consists of 27.2% solubilized mannan oligosaccharides, 17% crude protein, 3.4% ash, and 8% water. In addition to the control diet, three experimental diets were developed based on the control formulation to include the commercial MOS source, replacing wheat flour at different inclusion levels: 1.0 g (0.27 g mannans), 2.0 g (0.54 g mannans), and 4.0 g (1.08 g mannans) of solubilized MOS per kg of feed. These experimental diets were designated M1.0, M2.0, and M4.0, respectively. Shrimp, initially weighing 3.00 ± 0.04 g at a density of 100 shrimp $m^{-2}$, were randomly distributed and fed four times a day for 60 days. The shrimp weight (n = 20) was monitored every 10 days to assess growth and adjust the amount of feed. On day 30 and at the end of the experimental period, all shrimp were counted, and the following parameters were calculated: final weight, feed conversion ratio (FCR), survival rate, and yield.

**Table 1.** Performance of *P. vannamei* juveniles fed control and test diets with commercially solubilized mannanoligosaccharides in a synbiotic system for 60 days.

| Variables | Treatments | | | |
|---|---|---|---|---|
| | C | M1.0 | M2.0 | M4.0 |
| Final weight (g) | 8.86 ± 0.13$^{c}$ | 10.87 ± 0.26$^{a}$ | 9.30 ± 0.13$^{b}$ | 8.39 ± 0.17$^{d}$ |
| Survival (%) | 90.50 ± 1.50$^{a}$ | 91.67 ± 5.51$^{a}$ | 93.00 ± 3.00$^{a}$ | 73.00 ± 2.00$^{b}$ |
| Growth week $g^{-1}$ | 0.68 ± 0.01$^{b}$ | 0.91 ± 0.03$^{a}$ | 0.73 ± 0.02$^{b}$ | 0.63 ± 0.02$^{c}$ |
| kg $m^{-3}$ | 1.0 ± 0.01$^{c}$ | 1.25 ± 0.09$^{a}$ | 1.08 ± 0.02$^{b}$ | 0.77 ± 0.02$^{d}$ |
| kg $ha^{-1}$ | 8,014 ± 131$^{c}$ | 9,967 ± 719$^{a}$ | 8,644 ± 161$^{b}$ | 6,182 ± 51$^{d}$ |
| FCR | 1.70 ± 0.01$^{b}$ | 1.20 ± 0.14$^{d}$ | 1.50 ± 0.02$^{c}$ | 2.10 ± 0.10$^{a}$ |

Data are expressed as mean (n=3) ± standard deviation. The results were analyzed with ANOVA ($p \leq 0.05$) followed by the Tukey test. Mean values on the same line with different superscripts differ significantly.

*(Continued on next page)*

**Results**

At the end of the 60-day experimental period, significant differences were observed in shrimp performance between the treatments (Table 1). Diets supplemented with solubilized MOS, particularly M1.0 and M2.0, showed better results compared to the control group. The M1.0 treatment exhibited the highest average final weight (10.87 ± 0.26 g), significantly higher ($p < 0.05$) than the control group (8.86 ± 0.13 g). This group also had a higher weekly growth rate (0.91 ± 0.03 g $week^{-1}$) and better productivity, (1.25 ± 0.09 kg $m^{-3}$, 9,967 ± 719 kg $ha^{-1}$), when compared to other treatments. The feed conversion ratio (FCR) was most efficient in the M1.0 treatment (1.20 ± 0.14), significantly lower than in the control and other MOS diets. Survival was also higher in the M1.0 and M2.0 diets (91.67% and 93.00%, respectively), while the lowest value was recorded in the M4.0 group (73.00%).

**Conclusion**

Supplementation with 1.0 g and 2.0g of commercially solubilized MOS $kg^{-1}$ in the diet of *P. vannamei* raised in an intensive synbiotic system significantly improved final weight, feed conversion ratio and weekly growth rate compared to the control.

# PROBIOTICS AND SYNBIOTICS IN THE NURSERY CULTURE OF *Penaeus vannamei*: EFFECTS ON GROWTH AND ECONOMIC BENEFITS

Fabio Reis dos Santos[a]; Caio Rubens do Rêgo Oliveira[a]; Danielle Alves da Silva[a]; Gênison Carneiro da Silva[a]; Silvio Peixoto [a]; Marcos Santos[b]; Barbara Hostins[b]; Luis Otavio Brito[a*]

## Introduction

The synbiotic system (fermentation of prebiotics + probiotics = synbiotics) represents an innovative microbial biotechnology approach for recovery and utilization of waste in aquaculture, as it contributes to water quality management (acceleration of nitrification processes, reduction of organic load, *Vibrio* decrease and settleable solids) and the development of healthy microbial communities within the system. The prebiotic compounds such as rice, soybean, or wheat bran serve as fermentable substrates that enhance the colonization capacity and activity of probiotics. The probiotics typically include active microbial strains such as *Bacillus*, *Bifidobacterium*, *Lactobacillus*, or yeast species like *Saccharomyces cerevisiae*, which, when administered in adequate amounts, confer health benefits to the host. Its application has shown promising results in both intensive and semi-intensive aquaculture operations, particularly those with minimal water exchange. In this context, studies assessing the productive and economic benefits of probiotic and synbiotic applications during the nursery phase are critically important. These approaches may contribute to the economic sustainability of shrimp aquaculture by reducing production costs and improving juvenile quality. Therefore, this study aims to evaluate the effects of probiotic and synbiotic application strategies on water quality, presumptive microbial counts, and economic performance during the nursery phase of *Penaeus vannamei*.

## Material and methods

The shrimp with an average weight of 0.010 ± 0.001 g were transferred to 16 experimental tanks at a density of 280 PLs per tank (5,000 PLs $m^{-3}$) and cultured for 30 days. A completely randomized design was used, consisting of four treatments with four replicates each: Control (C): no probiotics or synbiotics; Probiotic (P): application of commercial probiotics strains activated with demerara sugar (2 hours); Synbiotic (S): application of rice bran fermented with commercial probiotic strains; Probiotic + Synbiotic (SP): alternating application of activated probiotics strains activated with demerara sugar (2 hours) and fermented rice bran containing probiotics. The experimental system consisted of 16 rectangular tanks with an operational volume of 56 L each. Before stocking, all tanks were filled with 50 L of seawater treated with sodium hypochlorite at 40 g $m^{-3}$ of active chlorine. Then, 6 L of inoculum were added from water an active shrimp nursery with the following physicochemical characteristics: total ammonia nitrogen (TAN) = 0.06 mg $L^{-1}$, nitrite-N = 0.03 mg $L^{-1}$, nitrate-N = 244.5 mg $L^{-1}$, total alkalinity = 140 mg $CaCO_3$ $L^{-1}$, pH = 8.0, settleable solids = 4.8 mL $L^{-1}$, orthophosphate = 23.6 mg $L^{-1}$, and salinity = 24.9 g $L^{-1}$. The synbiotic was prepared using a mixture of rice bran (as a carbon organic source), demerara sugar (also a C source), a commercial probiotic blend (*Bacillus subtilis* and *Bacillus licheniformis*, $5 \times 10^{10}$ CFU $g^{-1}$, PRO-W®, INVE Aquaculture Inc.), and sterilized water. After homogenization, the mixture underwent anaerobic fermentation for 24 hours followed by 24 hours of aerobic fermentation prior to use. At the end of the 30-day trial, shrimp performance was evaluated using the following parameters, calculated based on the surviving shrimp: Biomass gain (g) = Final biomass (g) – Initial biomass (g); Final weight (g) = Final biomass (g) / Number of surviving individuals; Feed Conversion Ratio (FCR) = Feed offered (g) / Biomass gain (g); Survival rate (%) = (Final number of shrimp / Initial number) × 100; Specific Growth Rate (SGR, % $day^{-1}$) = 100 × [(ln Final weight – ln Initial weight) / 30]; Yield (kg $m^{-3}$) = Final biomass (kg) / Tank volume ($m^3$). Input costs and shrimp performance parameters (final weight, productivity, and feed conversion ratio) were extrapolated to a 100 $m^3$ nursery tank to estimate the economic benefits of each treatment. Cost estimates for inputs were based on the following values: USD 72.02 per kg of probiotic; USD 0.58 per kg of synbiotic; USD 14.90 per kg of nursery feed; and USD 2.31 per 1,000 post-larvae. Economic benefits were calculated using the formulas: Feed cost (CR) = biomass gain × FCR × feed price per kg; Probiotic cost (CP) = 1 g/$m^3$ × 100 $m^3$ × 6 applications × probiotic price/kg; Synbiotic cost (CS) = 10 g/$m^3$ × 100 $m^3$ × 6 applications × synbiotic price/kg; PL cost (CPL) = 5,000 PL/$m^3$ × 100 $m^3$ × PL unit price; Total cost (CT) = (CR + CP + CS + CPL) / survival; Production cost difference (DCP) = control – treatment; Relative difference (DR) = DCP / control × 100.

*(Continued on next page)*

Table 1. Growth performance of *P. vannamei* in nursery phase with probiotic and/or synbiotic supplementation.

| Variables | Treatments | | | |
|---|---|---|---|---|
| | C | P | SP | S |
| Final weight (g) | 0.57±0.06[a] | 0.52±0.04[a] | 0.52±0.04[a] | 0.52±0.05[a] |
| Survival (%) | 82.57±2.81[b] | 94.47±5.50[a] | 97.12±4.05[a] | 98.22±3.55[a] |
| FCR | 1.26±0.11[a] | 1.22±0.09[a] | 1.19±0.05[a] | 1.17±0.07[a] |
| SGR (% day$^{-1}$) | 13.46±0.35[a] | 13.16±0.27[a] | 13.15±0.31[a] | 13.15±0.33[a] |
| Yield (kg m$^{-3}$) | 2.38±0.20[a] | 2.45±0.014[a] | 2.50±0.11[a] | 2.54±0.17[a] |

Data are expressed as mean ± standard deviation (n = 4). Different superscript letters in the same row indicate significant differences ($p < 0.05$).

**Results**

Supplementation with probiotic strains, with or without fermentation, significantly improved shrimp survival after 30 days. However, no significant differences ($p > 0.05$) were found for final weight, specific growth rate (SGR), feed conversion ratio (FCR), or yield (Table 1). Economic gains from probiotic and synbiotic supplementation, based on projections for a 100 m$^3$ nursery tank, ranged from USD 700 to USD 978, with relative cost reductions of 10–14% compared to the control (Table 2).

**Conclusion**

In this study, survival at the end of the nursery phase was significantly improved by *Bacillus* applications. The use of 1 g m$^{-3}$ ($10^{10}$ CFU g$^{-1}$) every five days enhanced and yielded economic benefits (increased revenue and relative cost difference) compared to the control. However, the greatest economic benefits were achieved with synbiotic applications.

# EFFECT OF MICROALGAE AND PROBIOTIC ENRICHED BIOFLOC ON STRESS RESPONSES OF *Mugil cephalus* UNDER OXYGEN AND DENSITY CHALLENGES

J. Brol[1]*, X. Lekube[2], M. Sanz-Latorre[2], A. Tomás-Vidal[1], R. Olivares-Perona[1], M. Jover Cerdà[1], S. Martínez-Llorens[1], D. S. Peñaranda[1]

**Introduction**

One of the major challenges in aquaculture is ensuring the sustainable expansion of the sector. In this context, several efforts have been directed toward investigating the application of Biofloc Technology (BFT) for a range of species. BFT is an example of sustainable aquaculture due to minimal water exchange and for enabling the recycling of nutrients, which are converted into bacterial protein (bioflocs). The rearing of omnivorous species in bioflocs has shown promising results, mainly due to the ability of these animals to take advantage of the biofloc as a complementary food source. Furthermore, research on *Mugil cephalus*, a native species of the Mediterranean and one of the promising candidates for aquaculture among omnivorous fish in this region, has also demonstrated that it can adapt well to biofloc. Thus, as BFT is a closed system, the introduction of functional additives in the water can be an interesting way to further enrich the system and, potentially, enhance the immune responses of the animals, for instance, through the addition of microalgae and probiotics. Therefore, the objective of the present study was to evaluate the effect of microalgae *Chlorella* and probiotic *Bacillus* addition on stress responses under oxygen and density challenge.

**Material and Methods**

For the experiment, 180 animals with an initial weight of 91,7 ± 22,4 grams were distributed in 12 circular tanks filled with 800 L of water at a salinity of 20 (10% of water was composed of a mature biofloc inoculum). The trial included 4 treatments in triplicate: microalgae addition (Microalgae), probiotics addition (Dark+Prob), microalgae and probiotics addition (Micro+Prob), and a control, just biofloc (Dark). The light restriction was used in Dark and Dark+Prob treatments to establish a heterotrophic system, while in the Microalgae and Micro+Prob treatments, a 12:12h photoperiod was used to maintain the microalgae and a mixotrophic system. The probiotic (Sanolife PRO-W *Bacillus subtilis* and *B. licheniformis*) and the microalgae (*Chlorella vulgaris*) were added to the corresponding treatments once a week, at 1g/$m^3$ and 6L/tank at 1A (corresponding to 18 x $10^6$ cells/ml), respectively. A commercial feed (DIBAQ - 3.5 mm) with 30% crude protein and 7% crude fat was provided three times daily at a 2 %/d feeding rate. The trial lasted 41 days. At the end of this period, the animals were exposed to a 4-hour stress challenge, followed by 24 hours of recovery, when the parameters were restored to standard levels. For the stress challenge, the animals were kept in a condition of Hypoxia (dissolved oxygen 2mg/L) + High density (50 kg/$m^3$). Before the stress, immediately after it, and at the end of the 24-hour recovery period, blood and liver samples were collected to analyze cortisol and enzymes of oxidative stress (n=2 animals per tank/time). Results were analyzed using a repeated measures ANOVA, considering the factors treatment and sampling time. Mauchly's test of sphericity was applied, and significant differences were verified by applying Fisher's LSD test at a 95% significance level ($p < 0.05$).

**Results and discussion**

At the end of the 41-day experimental period, the animals showed 100% survival in all treatments. Similarly, the stress challenge did not result in mortality. Regarding oxidative stress enzymes, the hypoxia and high-density challenge did not alter significantly the activity of the superoxide dismutase (SOD), although, among the groups, the Micro+Prob treatment was the one with the highest initial activity (0h). In contrast, the enzyme Catalase (CAT) was significantly reduced in all groups, except microalgae. After 24 hours of recovery, only the Dark group showed no restoration in CAT activity, which remained significantly lower than the Micro+Prob group. The stress condition increases glutathione peroxidase (GPx) activity in all groups. Only the Microalgae group demonstrated recovery of enzymatic activity to levels comparable to the basal condition (0h). With respect to cortisol, the challenge led to a significant increase in this parameter in all groups. Although the addition of microalgae and probiotics had a protective effect compared to the control, there was a lower increase in cortisol.

*(Continued on next page)*

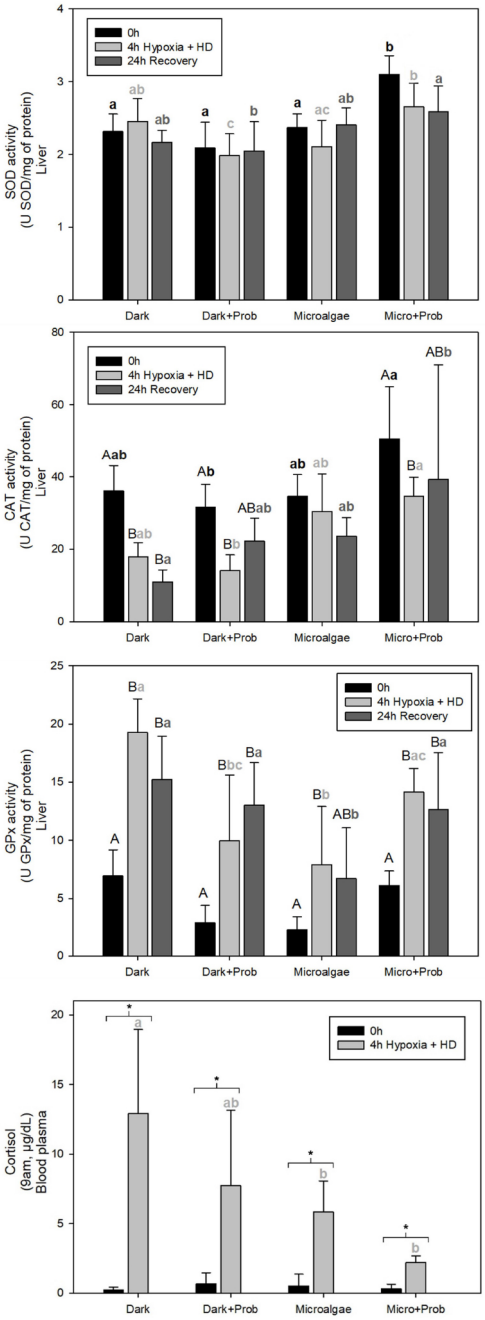

**Fig 1.** Activity of antioxidant enzymes in the liver of *Mugil cephalus*. (a) SOD, (b) CAT, (c) GPx and Cortisol level in the blood plasma (d). Different uppercase letters indicate significant differences among sampling times within the same treatment, and lowercase letters indicate significant differences between treatments at the same time point. For cortisol levels, '*' indicates significant differences within groups. A level of 5% ($p < 0.05$) was used for all analyses. Data are expressed as mean ± standard error (n=6).

There are few studies available on the inoculation of microalgae directly into biofloc and the associated oxidative stress response. On the other hand, many studies using *C. vulgaris* supplemented in fish diets report an improvement in the antioxidant capacity of the animals, mitigating the effects caused by oxidative stress. These findings agree with the results found in this study. One of the arguments behind the protective effect of *C. vulgaris* is related to pigments, such as carotenoids, which function against the reactive oxygen species generated under stressful conditions, performing a scavenging role. The use of probiotics is well established in BFT, especially in marine shrimp farming. The gender *Bacillus* is one of the most used in aquaculture, improving immunity and health status. Considering our results, the combination of the probiotic with microalgae led to improvements in the analyzed parameters when compared to the probiotic-only group. This was evidenced by a more effective antioxidant enzyme activity and a reduced increase in cortisol levels. In conclusion, combining microalgae and probiotics into the BFT demonstrates significant potential and an effective strategy to improve animal health in response to stress conditions.

# COMPARATIVE BENCHMARKING OF ELECTRIC VS. DIESEL AERATION IN SALMON AQUACULTURE

Adam J. Brooker, Adam Shargool, Wesley Malcorps, Stephanie Horn, Joshua Garrett, Julius Garrett and Richard Newton

Institute of Aquaculture
University of Stirling, FK9 4LA, UK
Email: a.j.brooker@stir.ac.uk

Aeration is a critical intervention in open-net-pen salmon aquaculture, used to maintain water quality and support fish welfare during periods of environmental stress. Conventional diesel-powered aeration systems, while effective, are energy-intensive, costly, and contribute significantly to greenhouse gas emissions. Here, we evaluate a novel electric-powered smart aeration unit (Pneuma) as a low-cost, energy-efficient, and environmentally sustainable alternative.

A trial was conducted at a commercial salmon net-pen site in Scotland to benchmark the performance of the Pneuma system against a standard diesel compressor, both running continuously. Over a two-week period in November 2024, two pens were aerated using the two systems, with air diffusers deployed at 7m depth. The trial aimed to assess operational efficiency, air delivery, and environmental impact in commercial aquaculture conditions.

Water quality was monitored using sensors deployed at multiple depths and locations within each pen capturing high-resolution data on dissolved oxygen, temperature, salinity, and chlorophyll. Power consumption and air output were recorded using inline airflow meters and power monitors, and diesel consumption was recorded manually. Additional environmental data, including tidal regime, turbidity and weather conditions, were also collected to contextualise system performance.

The trial provides a robust dataset for comparing the operational efficiency and environmental footprint of electric versus diesel aeration systems. The findings will inform a life-cycle assessment of the two systems. Building on this work, a second trial will run over 12 months to evaluate the impact of on-demand electric aeration on fish health, welfare, and performance compared to conventional diesel aeration. Outputs from this project will support the development of sustainable, scalable aeration strategies for the salmon aquaculture sector.

# EFFECT OF OREGANO ESSENTIAL OIL AND QUILLAJA SAPONIN EXTRACT ON THE POLAR TUBE EXTRUSION ACTIVITY OF SHRIMP MICROSPORIDIAN *Enterocytozoon hepatopenasei*

L. Brown*, O. Itsathitphaisarn, K. Sritunyalucksana, R. Suebsing and D Thaiue

Anpario plc, Worksop, United Kingdom
Center of Excellence for Shrimp Molecular Biology and Biotechnology (CENTEX Shrimp), Thailand
Email: lawrence.brown@anpario.com

## Introduction

Oregano essential oil (OEO) has been widely shown to support the health and productivity of various production species. Orego-Stim Forte (Anpario plc) is a commercial additive containing OEO and *Quillaja saponaria* extract. The trial objective was to determine whether this feed ingredient can inhibit the polar tube extrusion of *Enterocytozoon hepatopenasei* (EHP) spores that infect shrimp and cause significant economic losses to production.

## Materials and Methods

The study consisted of two phases. Phase one aimed to determine the inhibitory effect of the test ingredient on the polar tube extrusion activity of EHP spores. Concentrations ranged from 500 to 4000ppm with 30 minute contact time. For phase two, the infectivity of ingredient-treated EHP spores was tested following oral intubation of live shrimp. The SWP-qPCR method of hepatopancreas samples was used to determine the EHP replication levels of those spores fed orally to shrimp after 9-10 days.

## Results

For both low and high-salinity sourced EHP spores, no polar tube extrusion was detected when exposed to ≥2000ppm of the test ingredient (Figure 1).

Second phase results were collected following oral intubation of shrimp with ingredient-treated EHP spores from the first phase of the trial. SWP-qPCR of hepatopancreas samples revealed no infectivity of treated EHP spores when exposed to ≥2000ppm and ≥1000ppm concentrations from low and high salinity sources respectively.

## Summary

The test ingredient at ≥2,000ppm, containing OEO and quillaja saponin extract, inhibited polar tube extrusion of EHP spores *in-vitro*. Oral inoculation of treated spores at ≥2,000ppm confirmed inactivity since no replication was detected following SWP-qPCR of shrimp hepatopancreas samples 9-10 days post-injection.

# UNLOCKING COMMERCIAL SCALE GENOME EDITING

Debbie Plouffe*, John T. Buchanan, Matthew Josephson, Ashutosh Pudasaini, Yehwa Jin, Stephan Samu, Brandon Tsai

The Center for Aquaculture Technologies
8445 Camino Santa Fe, Suite 104
San Diego, CA, 92121 USA

dplouffe@aquatechcenter.com

Genome editing technologies, particularly those utilizing Site-Directed Nuclease 1 (SDN-1), are poised to transform aquaculture by enabling precise, efficient modifications to traits critical for productivity and sustainability. Traits such as sterility, accelerated growth, and yield can now be enhanced at scale in a single generation, offering clear commercial advantages. Recent breakthroughs in high-throughput genome editing—including somatic cell editing efficiencies exceeding 95% and scalable production of sterile fish—are driving the transition from research to industrial application. However, the path to global adoption is shaped not only by technical success, but by regulatory readiness.

The regulatory status of genome-edited animals, particularly those generated using SDN-1 approaches that do not introduce foreign DNA, varies widely across jurisdictions. While some countries have opted not to regulate SDN-1 organisms as genetically modified, others maintain strict oversight or lack clear guidance—posing potential barriers to commercialization and international trade. For export-oriented aquaculture producers, the regulation of the products of genome editing can directly impact market access and return on investment.

This presentation synthesizes current technical progress in commercial genome editing with emerging regulatory frameworks, and explores their implications for industry adoption, breeding program integration, and global trade. It emphasizes the urgent need for international regulatory alignment to unlock the full potential of genome editing and ensure that innovations translate into sustainable growth and competitiveness in aquaculture.

# SKIN TRANSCRIPTOMIC ANALYSIS IN ATLANTIC SALMON, EUROPEAN SEABASS, AND RAINBOW TROUT UNDER TRANSPORT-INDUCED ACUTE STRESS

**Introduction**

Fish transport is a widely used and unavoidable essential practice in aquaculture for purposes such as stocking, breeding, and growth. However, this process often exposes fish to acute stress, which can significantly affect their physiology and overall welfare. The severity of transport-induced stress can vary depending on the initial health status of the fish and transportation conditions, including duration, stocking density, temperature, water quality, and ammonia concentration. While transport rarely causes immediate mortality, secondary and tertiary stress-related responses can compromise both specific and nonspecific immunity, increasing susceptibility to disease and osmoregulatory imbalances, which may lead to mortality. Current methods for assessing immune and health status rely on invasive procedures (e.g., blood and tissue collection). Established welfare indicators, which help assess how well fish needs are met, are often observed too late to enable timely intervention, and remain limited for many farmed species. Further research is needed to understand how common aquaculture practices, such as transport, impact farmed fish.

**Experimental design and methodology**

To investigate the molecular signatures following acute stress, three key European aquaculture species – Atlantic salmon (*Salmo salar*, AS), European seabass (*Dicentrarchus labrax*, ES), and rainbow trout (*Oncorhynchus mykiss*, RT) were submitted to transport induced stress. The transportation trials were designed to simulate current transport conditions specific to each species. Skin tissue samples were collected at three time points: before transport, immediately after stress exposure, and following a 24-hour recovery period. RNA sequencing (RNA-seq) followed by differential gene expression (DGE) analysis and functional enrichment were performed to examine transcriptomic responses.

**Results and future prospects**

A comparative analysis across species revealed shared molecular pathways: mitogen-activated protein kinase (MAPK) signaling pathway was enriched in all three species, and ErbB and FoxO signaling pathways were enriched in AS and RT. A set of common differentially expressed genes was also observed, including 36 that were upregulated in response to stress. Among the upregulated genes are several involved in key biological functions such as immunity, apoptosis, stress modulation and epithelial regeneration. These findings offer valuable insights into conserved stress response mechanisms. Ongoing research will incorporate proteomic analysis of skin mucus and miRNA profiling from water samples to provide a more comprehensive understanding of the underlying biological processes and to support the identification of potential biomarkers for use in minimally invasive biosensors.

# EARLY-LIFE MICROBIAL DYNAMICS IN BARRAMUNDI HATCHERIES REVEALED BY FLOW CYTOMETRY AND 16S PROFILING

Ngoc Minh Ngan Bui [a,b], Tom Defoirdt [a], Nico Boon [a], Ruben Props [b]

[a] Center for Microbial Ecology and Technology (CMET), Ghent University, Frieda Saeysstraat 1, 9052, Ghent, Belgium
[b] Kytos BV, Technologiepark-Zwijnaarde 82, 9052 Ghent, Belgium

Barramundi (*Lates calcarifer*), native to the Indo-Pacific, has rapidly become the fastest-growing aquaculture species worldwide. However, maintaining stable production during the larviculture stage remains challenging, with larval mortality often reaching 100%. As hatchery management practices play a crucial role in regulating water microbiota, understanding microbiome dynamics is essential for improving survival rates. From day post hatch (DPH) 0 to DPH 17 at a commercial barramundi larviculture facility in Vietnam, microbial dynamics and community assembly in rearing tanks were analyzed using flow cytometry (FCM) and 16S rRNA gene amplicon sequencing. The analysis revealed persistent tank-specific differences in microbial communities that fluctuated over time. Stochastic factors played a significant role in microbial assembly, leading to variability between tanks even under similar operational conditions and underscoring the complexity of microbial community dynamics in larviculture systems. Flow cytometry and 16S rRNA sequencing showed moderately correlated diversity metrics and captured comparable overall trends in community composition, reflecting their potential complementarity in monitoring microbial dynamics. This underscores the potential of FCM as a complementary, rapid, and cost-effective approach for monitoring microbial community dynamic in aquaculture.

# DOES THE EMBRYONIC ENVIRONMENT IMPACT SMOLTIFICATION OF ATLANTIC SALMON (*Salmo salar*)?

E. Burgerhout[1*], R.S. Berg[1], A. Striberny[1], C.V. Henkel[2], C.C. Lazado[1]

[1]Nofima, Tromsø, Norway

Email: erik.burgerhout@nofima.no

## Introduction

The Atlantic salmon industry is challenged by large losses at sea, especially during the first months after the transfer from freshwater to seawater, which is often attributed to a poor smoltification status of the fish. Although a vast array of research is currently directed towards the understanding of the process of smoltification, alternative solutions to the problem may lie with manipulations of the early embryonic environment. It has been shown that the embryonic environment plays a crucial role in the performance of fish later in life. For example, temperature during early life appears to influence growth and immune function. Here we explore whether embryonic temperature impacts the smoltification process of Atlantic salmon.

## Materials and methods

Atlantic salmon embryos were exposed to different temperatures (4C and 8C) between fertilization and the 'eyed-stage'. Afterwards, similar temperature profiles have been applied. Smoltification was induced using a standard photoperiod regime. At consecutive time points gene expression levels of smoltification and oxidative stress markers were analysed in, respectively, gill and liver tissue. Hepatocytes of postsmolts were isolated and exposed to various stressors. Furthermore, blood serum metabolomics are currently being analysed.

## Results

Our preliminary results show that performance with respect to growth was not significantly impacted by embryonic temperature. Whereas the expression levels of the smoltification markers *nka1a* and *nka1b* in the gill showed similar patterns between the two temperature groups, *s100a* and *cftr2* showed opposite patterns. The oxidative stress marker *gpx* increased in the low temperature group, while *cat* and *cu/znsod* decreased over time in the 8C group with respect to the 4C group. Hepatocytes showed little differences between the embryonic temperature groups in their response towards hydrogen peroxide, polyIC or LPS.

## Conclusion

In order to improve the robustness of Atlantic salmon during its later life phases, the embryonic environment should be taken into consideration. It appears that the embryonic temperature may influence smoltification.

**Introduction**

Fishponds are essential ecosystems inhabited by many different species and serving commercial and non-commercial functions. Therefore, the management of fishponds can be a crucial factor affecting all the organisms inhabiting a given pond, as well as the physicochemical parameters of the pond water.

In this study, we investigated the effects of traditional (business as usual, BAU) and adjusted fishpond management (natural production, NP; natural production with supplementary feeding, NPF) on biota diversity and its seasonal development (macrozoobenthos, zooplankton and phytoplankton), the development of physicochemical water parameters, and the food source preferences and movement ecology of common carp.

**Materials and Methods**

To evaluate the impact of above-mentioned management strategies, four ponds were monitored monthly throughout the vegetation season over a period of three years (2021–2023). At each sampling point, the entire biota of the fishpond (fish, macrozoobenthos, zooplankton and phytoplankton) was sampled. In addition, physicochemical water parameters were monitored over the same period. To reveal the movement ecology of common carp, acoustic telemetry was employed. Additionally, stable isotopes and a fatty acid approach were employed to reveal the common carp's feeding preferences. The management of fish stocks was based on the natural production of the given ponds and the level of supplementary feeding planned.

**Results**

***Biotic communities*:** Fishpond management significantly impacted the seasonal development of the macrozoobenthos, zooplankton, and phytoplankton communities. Macrozoobenthos communities were the most sensitive to differences among BAU, NP and NPF, while zooplankton and phytoplankton communities were less sensitive.

***Water physicochemical parameters:*** Fishpond management had a significant impact on the physicochemical parameters of the water. In addition, the seasonal development differed between BAU, NP and NPF management. The most important of parameters affected by pond management were dissolved inorganic nitrogen, chlorophyll a, and total phosphorus.

***Common carp food source preferences**:* The preferred food sources changed over the season, regardless of the type of pond management. In NP management, common carp simply follow the most abundant food source. Nevertheless, when supplementary feeding was applied, the common carp utilized it at a higher rate, regardless of the abundance and biomass of other potential food sources.

***Common carp movement ecology*:** The activity and spatial use of carp changed over time, influenced by temperature, food availability, and stocking density. Their activity peaked in spring and early summer, with the highest levels occurring at night and dusk. During warmer months, the fish favored shallow areas (less than 0.5 meters deep), probably due to thermoregulation, oxygen levels or access to prey. Variability in the use of foraging sites and food composition among individuals correlated with growth, highlighting the importance of behavioral traits in resource acquisition.

*(Continued on next page)*

**Discussions**

This study highlights the complex interactions between fishery management practices and the aquatic communities of Central and Eastern European carp ponds. The management of fishponds is a key factor influencing the communities that inhabit them, as well as the physicochemical parameters of the water, the movement ecology of common carp and their food source preferences.

While the ponds may appear similar, the combination of environmental and human-induced factors has caused them to evolve in slightly different ways. Fish stocking based on the pond's natural production and proper supplementary feeding (here calculated to achieve a net production of 220 kg/ha of carp from additional feeding) does not negatively affect the communities and temporal trends of zooplankton and macrozoobenthos.

meredith.burke@stir.ac.uk

## Introduction

Aquaculture continues its global expansion, reaching a record production of 130.9 million tonnes in 2022, valued at USD 312.8 billion (FAO, 2024). As the industry grows, more sophisticated technology is needed to monitor farms and ensure their sustainability. Using behaviour as a non-invasive monitoring tool, particularly when combined with artificial intelligence (AI) and machine learning, offers new opportunities for real-time farm management and improved welfare outcomes (Feng et al., 2024). The growing adoption of computer vision has further enabled the use of cameras and image-based systems with algorithms to extract and analyse behavioural data in a non-invasive and cost-effective manner (Georgopoulou et al., 2021). These technologies allow for continuous observation of fish, providing insight into group dynamics in commercial farms that are otherwise difficult to monitor.

Building on a preliminary study conducted in 2023 (Burke et al., 2025; Burke et al., *in prep*), which identified behavioural changes associated with poor gill health in Atlantic salmon across 2 Scottish farms, the present study aims to further investigate the relationship between group behaviour and gill health in commercial sea cages. This expanded research includes additional sites across Scotland and integrates a broader range of welfare indicators to corroborate these past findings. It also explores potential contributing factors to gill health issues (e.g. environmental parameters, harmful plankton, micro-jellyfish) to better understand variation in onset across cages and farms.

## Methods

In the preliminary study, cameras were deployed at 2 Scottish Atlantic salmon farms. Cages at each farm had a camera used for feeding located in the centre of the cage at mid-depth. An algorithm was created by Observe Technologies to process video footage from these cameras and transform it into behavioural data, termed 'activity', which encompasses fish abundance, speed, and shoal cohesion. Daily validation occurred for the duration of the study, whereby experts compare the videos to output from the algorithm. Additionally, gill health scores were evaluated weekly at both sites through the visual sampling of 10 fish in each cage (0 = healthy gills, 5 = necrotic tissue). During the summer 2023, gill health issues arose at both farms, leading to fish stress which was evident in the behavioural data. For the present study, cameras with the algorithm were deployed at 9 additional farms which consisted of between 10-14 stocked cages. Along with the gill health scores recorded by the farmers, the AGD histopathology results, operational welfare indicators, feeding and environmental parameters (e.g. temperature, oxygen, plankton, jellyfish) will be analysed.

## Results and Discussion

Preliminary findings from an earlier phase of this project demonstrated a potential relationship between group-level behavioural patterns (activity) and gill health in Atlantic salmon (Fig. 1). This as also associated with decreased feeding rate and increased mortality.

The current study expands on this by incorporating additional sites. It is anticipated that consistent changes in behavioural metrics such as activity and spatial cohesion will be observed in association with deteriorating gill condition. If confirmed, these findings will support the development of real-time, non-invasive welfare indicators. Final results will be available for presentation and discussion at the conference.

**Introduction**
Diseases continue to be a major challenge for the European sea bass industry in the Mediterranean region. While traditional selective breeding for disease resistance based on estimated breeding value is often costly and complex, genomic selection utilising high-density SNP genotyping combined with functional annotation data offers a more efficient approach to improve genetic resistance that supports sustainable aquaculture across multiple generations and diverse populations. The aim of this study was to evaluate whether integrating functional annotation data into genomic prediction models enhances the accuracy of predicting resistance to viral nervous necrosis (VNN) in European sea bass (*Dicentrarchus labrax*), using both Bayesian and machine learning methods.

**Material and methods**
A 29-day VNN challenge test was performed on 990 juvenile European sea bass (6-20g) and mortality was recorded as a binary trait. The experimental fish were genotyped using the Med-Fish SNP array (27,740 SNPs), while the parents and 40 experimental fish were whole-genome sequenced (6,072,853 SNPs), allowing whole-genome imputation for all experimental fish.

SNP filtering was based on: (1) predicted regulatory regions identified by ATAC and ChIP-seq data in different tissues; (2) Ensembl annotations of open chromatin, promoter and enhancer regions; and (3) classification of coding and non-coding variants (including intergenic, intronic, upstream, downstream, 5' UTR, 3' UTR, and synonymous variants) using the Ensembl Variant Effect Predictor. The control dataset included SNPs that were located in quiescent regions in all tissues and were not categorised into one of the Ensembl functional categories. All analyses were performed both excluding and including chromosome 3, which harbors a major QTL for VNN resistance.

Genomic prediction of genetic merit for mortality was performed using Bayesian threshold models as implemented in GIBBSf90+/BLUPf90+. Each analysis was repeated 100 times, with 2000 SNPs randomly selected per repetition. To mimic a realistic genomic selection scenario, where the prediction equations are trained on a reference population that is distantly related to the selection candidates, prediction accuracy was assessed using two-fold cross-validation. The folds were constructed to minimise relatedness between clusters and maximise relatedness within clusters.

Machine learning methods, including extreme gradient boosting (XGBoost), COMBI, deepCOMBI and Chaos Game Representation (CGR), were also tested to gain insight into their performance in classifying the mortality phenotype. In this case, three datasets were created based on predicted regulatory regions identified from ATAC and ChIP-seq data: regions active in at least 80% of tissues (Active80), 50% of tissues (Active50) and 10% of tissues (Active10). The same two-fold cross-validation strategy was used to assess model accuracy.

*(Continued on next page)*

**Results and discussion**

Results showed significantly improved performance when SNPs in active regulatory regions, or in open chromatin, enhancer, and promoter regions, were combined with causal variants, with prediction accuracy increasing by up to 20.8% compared to the control dataset. In contrast, when causal variants were excluded, the results were more variable, ranging from a 12.6% decrease to a 15.1% increase in prediction accuracy. Better performance compared to the control dataset was observed when using coding and non-coding variants, with a 4–6% increase in prediction accuracy when causal variants were not included, and a 20–23% increase when causal variants were included.

Machine and deep-learning methods showed variable performance across functional datasets. Higher F1-scores were observed with Active50 and Active10 sets than those obtained with the control dataset (0.66-0.74 vs 0.42-0.62 for Active50, 0.64-0.76 vs 0.61-0.74 for Active10). CGR demonstrated efficient discriminative capability between mortality categories using the active datasets.

These findings underscore the value of functional annotation data in enhancing genomic prediction accuracy for VNN resistance. More broadly, the results suggest that functional annotation data can improve the robustness and transferability of genomic prediction models for complex economic traits in aquaculture. By leveraging biologically relevant SNPs, breeding programs can increase prediction accuracy across generations and genetically diverse populations, ultimately supporting more efficient and sustainable genetic improvement in fish farming.

Metal-based nanoparticles (NPs), including quantum dots (QDs) and rare earth metal (REM)-based nanomaterials, are increasingly utilized in biomedical and environmental applications due to their unique physicochemical properties. QDs—typically composed of semiconductor materials such as CdSe/ZnS—exhibit exceptional fluorescence, making them ideal for cellular imaging and biosensing. Similarly, REM-based NPs, including those doped with europium ($Eu^{3+}$) or containing cerium ($Ce^{4+}$), are valued for their luminescent, redox, and catalytic behavior. Nonetheless, increasing attention is being directed toward the potential nanotoxicity and long-term environmental persistence of NPs, particularly due to their adverse effects on aquatic organisms. These concerns highlight the need for multiscale evaluation frameworks that consider NP morphology, concentration, and physicochemical interactions with aquatic organisms, including algae, crustaceans, and fish. Our results demonstrate that QDs can induce changes in the gut microbiota of *Salmo trutta fario* juveniles, inhibit the growth of the green algae *Desmodesmus communis*, and affect the heart rate of *Daphnia magna*. Furthermore, the effects of rare earth metal (REM)-based NPs on *D. communis* were dependent on the algal growth medium, while their impact on *D. magna* varied with NP concentration. As nanotechnology continues to advance across various sectors, further research is essential to balance innovation with environmental and biological safety, ensuring the responsible and sustainable application of nanoparticles.

## Introduction

*Solea senegalensis* is one of the most thriving species of marine large-scale culture in Europe and one of the threats that causes important economic losses is the infection by *Aeromonas salmonicida*. Although there are different types of vaccines produced for aquaculture, the majority that are used for bacterial pathogens are killed whole-cell preparations. Besides protection, vaccine delivery is an area where significant improvement is needed. Fish vaccination is mainly conducted by injection (intraperitoneal or intramuscular), soaking (bathing or spraying), or oral routes (1). Oral vaccination is highly pursued in aquaculture as is a cost-effective, and almost effortless delivery method, suitable for all stages of development (2, 3). Their efficacy is dependent on antigen content in the feed, resistance against gastric degradation and antigen adsorption/uptake in the gut. Oral vaccines have also the advantage of facilitating the implementation of a vaccination regime with boosters that avoid fish handling and stress. Here, we developed two experimental vaccines, including oral and intraperitoneal (ip.) formulations, and determine the capacity of the new vaccine formulations to provide protection against *A. salmonicida* in the sole compared with the standard ip. autogenous vaccine used currently.

## Material and methods

Two oral formulations with whole or particulate antigen (OV-W/OV-P) at two different doses (high-HD, low-LD), and an intraperitoneal vaccine consisting of a gel adjuvant emulsion with liposomes formulated also with whole or particulate antigen (LIPV-W/LIPV-P) were administered to cultured soles. Their effects were compared to the standard ip. vaccine (STV) formulated with and oil-based adjuvant. The efficacy of the vaccines was analyzed by challenging sole at 90-days post-vaccination by ip. inoculation with a lethal dose that was previously determined in a LD50. The relative percent survival was calculated using the formula: RPS = [1 – (% mortality in vaccinated fish/% mortality in control fish] x 100%. For leukocyte analysis, tissue and peritoneal single cell suspensions (40 µm pore size nylon mesh) were centrifuged onto a 30/51% discontinuous Percoll gradient. Labelled cells were analyzed in a CytoFlex flow cytometer. Real-time PCR was performed in a QuantStudioTM 3 System (Applied Biosystems).

## Results

Challenges with *A. salmonicida* three months after vaccination resulted in a 45-54% relative percent survival for both, the oral HD and the LIPV ip. vaccines, while the RPS of the STV was 18% (Fig. 1).

After immunization, only ip. vaccines activated gene expression related to the fish immune response and increased antibody production. Higher IgM specific titters against the bacteria were obtained in the serum of fish vaccinated with the novel LIPV formulas compared to the STV which correlates with the degree of protection. In contrast, no correlation was found between the degree of protection of the oral formulas and the IgM specific titters, indicating that other immune mechanisms are also involved in fish protection against the bacteria. $IgM^+$ B cells among the cell populations in the spleen and peritoneal cavity were quantified using flow cytometry. Higher percentages of $IgM^+$ cells were found in the peritoneal exudate of the groups vaccinated ip. compared to control at 7 days post-vaccination, including LIPV and STV, that cannot explain the differences in the degree of protection between both groups. As for expression studies, strong involvement of the markers for an inflammatory response were observed at 3 and 7 days post-vaccination only in the ip. vaccinated groups including *il-1b, il-8* and *hepcidin,* and no differences were found in the expression of markers for the specific humoral and cell-mediated responses at these early time-points.

*(Continued on next page)*

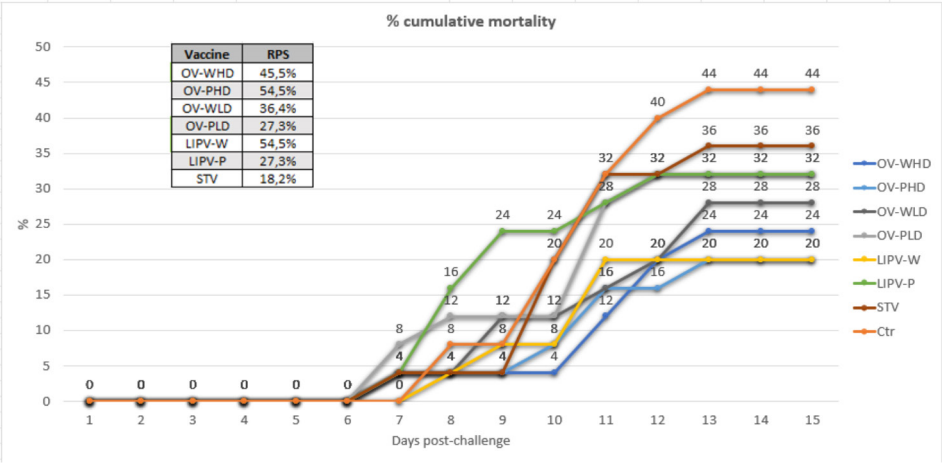

Fig. 1. Protection levels of the vaccines at 3 months post-vaccination. Cumulative mortality of *S. senegalensis* following ip. challenge with *A. salmonicida*. The RPS is indicated in the table. N = 25.

**Conclusions**

- Oral and liposome+gel-based adjuvanted vaccines confer longer-term protection than standard oil-based adjuvanted vaccines in sole against *A. salmonicida* subsp. *achromogenes*.
- Ip. vaccines induce classical systemic responses such as increment of specific antibodies in serum, recruitment of cells to the peritoneal cavity, and up-regulation of pro-inflammatory genes.
- The protective effect of the oral vaccine must rely on immune mechanisms different from those triggered by the ip. route.

**Introduction**

Gill structural integrity and functionality are essential for fish survival, performance, and overall fitness in wild and aquaculture environments. Inside open sea cages, farmed Atlantic salmon are vulnerable to a variety of gill-damaging stressors, such as jellyfish, harmful algae blooms, farm management practices, and infection. Gill lesions and diseases have led to significant economic losses in Atlantic salmon aquaculture globally.

Fortunately, recent findings show that Atlantic salmon gill can regenerate following damage, restoring respiratory and ion regulatory functions (Ghanizadeh-Kazerouni et al., 2024). Building on this discovery, the present study investigates transcriptomic changes in regenerating gill filaments over 20 weeks following resection.

**Materials and Methods**

Post-smolt Atlantic salmon maintained in freshwater were lightly anaesthetised with MS-222 and subjected to gill filament resections of either 30% or 50% of filament length. Control fish underwent anaesthesia without resection. Fish from the Control and Resected groups were terminally sampled at 1, 2, 4, 8, 12, 16, and 20 weeks post-resection to collect intact and resected filaments, respectively. The 50% resected filament group was chosen for RNA sequencing as that group was expected to show more robust transcriptomic responses.

Four to seven filaments per condition and time point were processed for total RNA isolation and submitted to Canada's Michael Smith Genome Sciences Centre (Vancouver, BC) for library preparation and sequencing on an Illumina NovaSeq 6000 (PE150, targeting ≥50 million reads per library). Raw data were quality-checked and analysed using an established bioinformatics pipeline (Eslamloo et al., 2022), and differential expression analyses were performed with DESeq2 comparing Control and Resected groups at each time point, using an adjusted p-value < 0.01 and requiring expression in at least half the replicates of at least half the groups.

**Results and Discussion**

During the trial, gill filament regeneration became evident by week 8 and reached an average of 34.2% regrowth by week 20, accompanied by restored $Na^+/K^+$-ATPase activity (Ghanizadeh-Kazerouni et al., 2024). In parallel, transcriptomic differences between Resected and Control filaments diminished as healing and regeneration progressed, with 2,574 differentially expressed genes (DEGs) at week 1 post-resection, 970 DEGs at week 2, 782 DEGs at week 4, 610 DEGs at week 8, 526 DEGs at week 12, 216 DEGs at week 16, and 273 DEGs at week 20.

A hierarchical clustering analysis helped identify distinctive regulation patterns over time among the DEGs, linked to specific biological processes via Gene Ontology enrichment analyses. Inflammation-related transcripts were markedly elevated at week 1 but declined rapidly thereafter. Genes involved in cell proliferation, migration, and differentiation—including pluripotent, epithelial, and neuroepithelial cells—were also highly expressed in early stages (weeks 1 & 2), consistent with immunohistochemical observations (Ghanizadeh-Kazerouni et al., 2024). A similar temporal pattern was observed for genes related to angiogenesis, mesenchymal cell transition, cytoskeletal organisation, and cell junction assembly.

*(Continued on next page)*

Notably, up-regulated DEGs associated with cellular energy metabolism and organ development displayed a progressive rise in transcript levels between weeks 1 and 8—coinciding with the occurrence of blastema-like structures (Ghanizadeh-Kazerouni et al., 2024)— followed by a decline and stabilisation by week 16. These patterns suggest a phased regeneration process, beginning with rapid immune resolution and activation of progenitor cells, followed by tissue patterning and structural remodelling.

DEGs with reduced transcript levels in the Resected filaments exhibited a progressive—though often incomplete—return towards Control-like expression over time. The most robustly over-represented biological processes among these genes included ion transport (e.g. chloride, potassium, and sodium), synaptic signalling and potentiation, and lipid metabolism—processes critical in establishing functionality.

Interestingly, a distinct cluster of downregulated genes showed transcript levels rising rapidly after week 2, surpassing those in Control filaments by week 4. This cluster was enriched for fibroblast growth factor (FGF) signalling and associated processes, including glycosaminoglycan metabolism, cartilage development, extracellular matrix (ECM) components, and ECM remodelling. This pattern might reflect parallel recruitment and activity of fibroblasts and chondrocytes during structural remodelling, supporting the re-establishment of filament architecture.

In summary, our RNA sequencing results describe the transcriptomic changes underlying gill filament regeneration in Atlantic salmon as a phased process, including immune resolution, progenitor cell activation, cell proliferation, and tissue remodelling and development. Further analyses will focus on genes correlated with regeneration rates to identify molecular drivers and potential markers of successful tissue restoration.

**Introduction**

Advancing sustainable aquaculture practices requires the replacement of finite marine-derived proteins in fish diets with alternative, eco-friendly sources to reduce environmental impact and reliance on limited resources. While plant-based proteins and land-animal by-products are already commonly used, their deficiency in taurine, a conditionally essential amino acid for marine fish, raises important nutritional and physiological concerns. Taurine plays a crucial role in several biological processes in fish, including growth and development during early life stages, osmoregulation, bile acid metabolism, and antioxidant defense (Aragão et al., 2022).

Throughout the production cycle, fish are exposed to various human-induced stressors, particularly during routine procedures such as grading and vaccination. These practices involve crowding, chasing, and air exposure, which can trigger acute stress responses. Such events may lead to significant physiological disruptions, including changes in endocrine function, which can negatively impact stress and antioxidant responses, potentially increasing mortality or disease susceptibility (Ciji & Akhtar, 2021)

Understanding how nutritional strategies can modulate stress responses is essential for improving fish welfare and promoting sustainable aquaculture practices. Thus, the aim of this study was to evaluate the effect of taurine supplementation in low fishmeal diets on oxidative status and stress response of European seabass following a stress challenge.

**Materials and Methods**

Three isonitrogenous, isolipidic and isoenergetic diets were formulated using practical ingredients: a control diet (**MARINE**), formulated as a premium diet rich in marine ingredients; a low fishmeal diet (**PAP**), containing only 5% fishmeal with marine ingredients replaced by animal by-products, namely poultry meal and poultry blood meal: and a diet with a formulation similar to the PAP diet but supplemented with 1% of L-taurine (**TAU**).

Triplicate groups of 23 juvenile European seabass (34.5 ± 7.4 g) were arbitrarily distributed into 100 L cylindrical tanks in a recirculating aquaculture system. Each diet was randomly assigned to three replicate tanks. Fish were fed by hand until apparent satiation, twice daily for 15 days. Tanks were supplied with filtered seawater at 20.1 ± 0.2 ºC. Dissolved oxygen, nitrogenous compounds and pH were checked and registered daily and maintained at levels within the recommended limits for the species. Fish were exposed to a natural summer photoperiod.

At the end of the feeding period, and before the stress challenge, five fish from each tank were sampled (plasma, liver, and anterior intestine) to assess the basal physiological status (**T0**). Immediately after this sampling, fish were subjected to an acute stress event (overcrowding, net chasing and one minute of air exposure) and were returned to their respective tanks. The same number of fish and biological samples that were collected at T0 were also taken at 1, 4 and 24 hours post-stress, thereafter referred to as **T1**, **T4** and **T24**, respectively.

*(Continued on next page)*

**Results and Discussion**

At T0, no significant differences were observed in the analyses conducted for either the stress response or antioxidant status, indicating that the replacement of fishmeal with animal by-products and the addition of taurine did not significantly affect the basal levels of these parameters. Regarding the stress response results, no significant differences were observed in glucose, cholesterol, lactate, or triglyceride levels at any time point. However, for cortisol, significant differences were detected at T1 and T24, with fish fed the TAU diet showing lower levels compared to those on the other two diets. These findings suggest that taurine supplementation at this level may exert beneficial effects by modulating cortisol release in response to stress.

As for the antioxidant status, in the liver, significant differences in catalase activity were observed at T1, with fish fed the TAU diet exhibiting significantly lower catalase activity compared to those on the other two diets. At the same time point, total glutathione levels were significantly higher in fish fed the MARINE diet than in those fed the PAP and TAU diets. Additionally, at T24, fish fed the MARINE diet showed significantly lower levels of lipid peroxidation compared to the other two groups. Regarding the anterior intestine, significant differences in catalase activity were observed only at T24, with fish fed the MARINE diet showing a significant increase in activity.

These initial findings suggest that diets rich in marine ingredients provide more effective protection against oxidative stress by reducing lipid damage and supporting both enzymatic (catalase) and non-enzymatic (total glutathione) antioxidant defenses. In contrast, the PAP and TAU diets exhibit more limited effects on antioxidant responses. However, taurine supplementation appeared to confer beneficial effects on the stress response. Therefore, while taurine supplementation may have the potential to enhance the resilience of fish fed low-fishmeal diets, further refinement of these formulations is needed to improve their ability to mitigate oxidative stress effectively.

**Introduction**
The intensive production practices in salmonid aquaculture have led to significant health challenges, predominantly from bacterial, fungal, and parasitic infections (Tobback et al., 2009; Du et al., 2015; Wahli & Madsen, 2018; Shreves et al., 2024). Conventional use of antibiotics and antiparasitic treatments has raised global concerns regarding antimicrobial resistance and ecological sustainability (FAO/OIE/WHO, 2006). This research aims to evaluate the efficacy of two organosulfur compounds, Propyl-Propane-Thiosulfinate (PTS) and Propyl-Propane-Thiosulfonate (PTSO), extracted from *Allium cepa*, as potential alternatives for managing these infections in rainbow trout (*Oncorhynchus mykiss*) and Atlantic salmon (*Salmo salar*).

**Materials and Methods**
*In vitro* assays, including disk-diffusion and Minimum Bactericidal/Fungicidal Concentrations (MBC/MFC), assessed antimicrobial and antiparasitic activities of PTS, PTSO, and their combination (PTS/PTSO). Pathogens tested included *Yersinia ruckeri*, *Aeromonas salmonicida*, *Lactococcus garvieae*, *Piscirickettsia salmonis*, and *Saprolegnia parasitica*. Antiparasitic efficacy was evaluated against adult *Caligus rogercresseyi* in controlled laboratory settings. Complementary *in vivo* studies involved dietary supplementation trials in rainbow trout to determine survival after pathogen infection.

**Results**
*In vitro* results showed substantial inhibitory activity against the targeted pathogens and parasites, with PTSO demonstrating consistently greater effectiveness compared to PTS. The combination of PTS/PTSO markedly reduced parasite viability, especially in early parasite developmental stages. *In vivo* dietary supplementation with PTS/PTSO significantly enhanced survival rates and decreased disease severity in challenged rainbow trout.

**Conclusion**
The findings underscore the promising antimicrobial and antiparasitic properties of PTS and PTSO, positioning these organosulfur compounds from onion as sustainable and effective alternatives for managing health issues in salmonid aquaculture. Further research is required to optimize delivery systems and compound stability under practical farming conditions.

## Introduction

Aquaponic production is recognized as a sustainable agriculture solution, effectively utilizing the nitrogen by-products from aquaculture as nutrients for fresh produce (Verma A.K., et al., 2023). AWARE (*Aquaponics from wastewater reclamation* GA N.101084245) aims to further this concept by establishing the first European Recirculation Aquaponics System (RAS) for using reclaimed water to grow fish (tilapia) and plants (lettuce) for human consumption. This study intends to assess the food safety of foods produced in a small-scale experimental recirculating aquaponics system that utilizes reclaimed water while ensuring animal welfare.

## Materials and Methods

**Aquaponics experimental system**: experiments were conducted in a small-scale, Recirculatory Aquaculture System (RAS) installed in Castellana Grotte coupled with a municipal wastewater plant. The experimental system comprised three different RAS modules, RAS1, 2 and 3. RAS1 operated using dechlorinated tap water (CONTROL), while RAS2 and RAS3 were supplied with reclaimed water. RAS were stocked with Nile tilapia (*Oreochromis niloticus)* and a 5 $m^2$ of crop planting surface with capacity for 90 lettuce plants (*Lactuca sativa* Batavian Red). Microbiological and chemical hazards, along with animal welfare, were monitored by collecting samples at the beginning (M0) and every three weeks at M1 and M2 between September and December 2024.

### Microbiological analysis

*Microbiological hazard analyses. Listeria monocytogenes*, *Salmonella* spp., *Escherichia coli* and intestinal enterocci were determined in tilapias and lettuces produced in the new aquaponics system accordingly with EU regulation (EC 2073/2005; EU 2020/2184; 2020/741) by following the standardized ISO methods. *Aeromonas hydrophila* and *Pseudomonas aeruginosa* were also included as non-regulated pathogenic bacteria associated to aquaponics foods (Dorick J. et al., 2024). The presence of several human enteroviruses, including Sapovirus (SaV), Norovirus (NoV GI and NoV GII), Hepatitis A (HAV), Hepatitis E (HEV) was determined by real time PCR following the ISO 15216-1; 2017. CrAssphage, and Pepper Mild Mottle Virus (PPMoV) was also assessed as indicators of fecal contamination in aquatic environments that can reflect the effectiveness of treatment systems (Gyawali, P. et al. 2019).

*(Continued on next page)*

*Microbiological characterization.* Total DNA, extracted from tilapia's gut and gills and lettuce's roots, in parallel with water and biofilter samples, was used for 16S rRNA gene metabarcoding aiming the characterization of the bacterial community and assessment of potential cross-contamination. In addition, the genotypes of bacterial isolates of tilapia and lettuce were compared.

***Chemical hazards analysis***: Regulated contaminants and maximum levels defined in the EU Regulation No 1881/2006 (e.g. nitrate, mycotoxins, certain metals (Pb, Cd, Hg, Sn), dioxins and PCBs, PAHs) and unregulated contaminants (CECs) were determined by means of ICP-MS, GC-HRMS and LC_HRMS.

***Animal welfare***: Animal welfare assessment was determined by combining growth performance, somatic indices, differences in inflammatory gene markers.

**Results**

***Microbiological analyses****: Regarding microbiological hazards,* no significant differences in food-borne pathogenic bacteria were observed between tilapias and lettuces produced with potable (RUN1) and reclaimed water (RUN2, RUN3). *L. monocytogenes* was only detected in the soil at M0. *Salmonella* spp. was detected by qPCR but its presence was not confirmed by the ISO method. *E. coli* and *Enterococcus* were quantified in tilapia, plants, and soil at the beginning of the experiment (M0). *Aeromonas hydrophila* and *Pseudomonas aeruginosa* were not detected. Regarding virus analysis, only NoV GI was detected in muscle al levels lower of the LoQ. Other enteric viruses including SaV, HEV or NoVGII were detected in internal organs mainly in M2. NoV GII and SaV, as well as PMMoV, were identified in the leaves of the lettuces in M2. Additionally, higher levels of PMMoV in Tilapias were observed in M2 compared to M0 and M1. Regarding *microbial characterization*, the bacterial community analysis evidenced distinct bacterial communities in tilapia and in lettuce, which were relatively stable during the experimental cycle. The hypothesis of possible cross-contamination between water, tilapia and lettuce was not confirmed based on the community analysis. However, the inspection of the genotypes of the bacterial isolates, which is more sensitive, may provide further information.

***Chemical hazards***: Initial results indicate that the levels of contaminants are well below the maximum levels defined in the EU Regulation No 1881/2006.

***Animal welfare****:* No significant differences in fish mortality were observed among the different treatments. The evaluation of growth performance revealed significant differences between RAS2 and RAS3 (ANOVA $F(2,6)=7.62$, $p=0.02$); however, these did not differ significantly from RAS 1. Similar patterns were observed for fish size. Fish in RAS 2 showed increased length, although the differences were not statistically significant (ANOVA $F(2,6) = 4.65$, $p = 0.06$). The hepato-somatic index indicated reduced liver weight in RAS1, but this difference was not significant ($F(2,6)=2.92$, $p = 0.13$). In contrast, the spleen-somatic index showed significant differences among treatments ($F(2,6)=12.5$, $p=0.007$). Specifically, RAS1 differed significantly from both the control ($p < 0.01$) and RAS 2 ($p = 0.01$).

**Conclusions**: the first conclusion is that microbiological risk analysis of tilapia and lettuce produced in the aquaponic system designed at AWARE using reclaimed water showed that these foods are safe. Additionally, there was no evidence of microbiological cross-contamination between water, tilapia and lettuce. Regarding chemical hazards, analysis indicate that the levels of contaminants are below the maximum levels defined in the EU-regulation. Finally, fish mortality remained unaffected across treatments, although physiological responses suggest differing resource allocation strategies.

## Introduction

Lesions in the skin are a major welfare problem for the fish and a big cause of economic losses for the salmon industry (Takle et al. 2015). Skin lesions, abrasions, and ulcers are the main entrance for pathogens. In these situations, skin wounds must be promptly treated in order to avoid negative impacts on fish (Ceballos et al. 2017 and Costa et al. 2018). The wound healing process is dependent on factors such as temperature, wound dimensions, stress, and importantly nutrition. However, few studies have investigated nutritional interventions that could potentially improve the regeneration of fish skin (Sveen et al 2019). The aim of this study was to test the effects of vitamin inclusion level on wound healing. To this end a skin wound healing model was created in salmonids to evaluate the molecular and biochemical process involved in the different phases of regeneration in rainbow trout.

## Material and Method

The trial was performed at the Research Centre for Animal Nutrition and Health (DSM Nutritional Products France). Eighty rainbow trout (*Oncorhynchus mykiss; initial body weight 63g*) were randomly allocated to two different experimental groups. The fish were fed 84 days with basal diet mimicking a Norwegian commercial recipe (control) or an Optimum Vitamin Nutrition (OVN) diet (Liu et al 2022) that differed from the control in higher vitamin level inclusions. Each treatment was given to two replicate groups of 20 fish Animals from the 2 diets were wounded after 28 days of feeding with the experimental diets corresponding to day 0 of the experiment. The fish were wounded with a punch biopsy tool, transversing the full thickness of the skin barrier on the left dorsal flank of the fish. The principal advantage of this model is that a deep wound involves both dermal and epidermal repair processes. The fish continued to be fed with the experimental feed until the end of the trial. Growth parameters, blood biochemistry, wound size, and the expression of 12 genes representative of the different phases of the wound healing process were monitored at day 0, 1, 3, 7, 14, 21, 28, 35, 49 and 56 days post wounded (dpw).

## Results

As expected, strong modulations over time were observed for all the blood parameters, except for phosphorus ($p=0.0870$) and sodium ($p=0.1035$). An increase in the size of the wounds on 1dpw, 3dpw, and 7dpw was observed. The return of the initial size of the wounds occurred for the two treatments between 7dpw and 14dpw. With high levels of vitamins diet a complete closure of all the wounds occurred 7 days before those of fish fed with control diet. After normalization of the size of the wounds to the 0dpw size for each fish, statistical differences were observed between the two treatments at 1dpw ($p=0.0028$), 3dpw ($p=0.0014$) and, 7dpw ($p=0.0072$). From 14dpw to the end of the trial, no differences were observed between the treatments ($p>0.05$) (Figure 1).

We were able to identify the progression of wound healing at the transcriptomic level. The re-epithelialization genes followed an expected pattern, but maximum expression was delayed. For MMP13 we observed maximum expression at 14dpw for diet J and 7dpw for control diet. Maximum expression of chemokine 4 ligands was observed at 3dpw for the two diets. This may reflect the fact that immune cells are less necessary at the very beginning of the wound healing process in our model. The inflammation step was reduced in this trial. The expression of serum amyloid A appeared early, at 3dpw for both diets. In addition, IL-1B gene expression levels were flat with many variations. Granulation tissue genes are also affected in our model. Instead of a continuously decreasing expression expected, we observed a maximum of expression at 14 days with the two diets. This could indicate a lack of activation of the gene at the very beginning of the wound. The genes involved in tissue remodeling (Col1a1a and Hyaluronisase-2-precursor) showed an expected profile, similar between the two diets.

*(Continued on next page)*

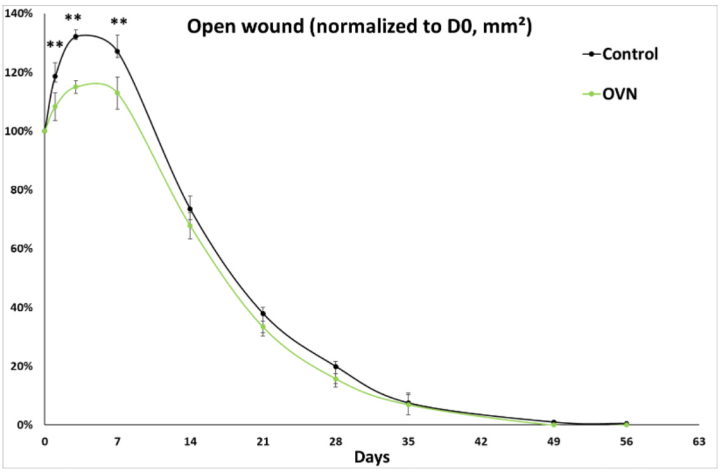

Figure 1: Size of the open wound over the time. * corresponds to significant differences between the treatments (**: $p<0.01$). Abbreviation: OVN, Optimum Vitamin Nutrition.

The genes involved throughout the wound healing process (Cytochrome P450 4F3 and Epigen precursor) showed also an expected expression profile, reflecting the success of the wound healing process. Interestingly, CD4 gene expressions were limited to T0 and 3dwp. The level of CD4 expression was lower with control diet K than with OVN diet.

**Conclusion**

The model presented was able to assess the difference between the inclusion levels of vitamins. In this trial based, we were able to observe differences macroscopically but also at transcriptomic level. And, it is clear that vitamins play a key in supporting wound healing. Then, the reduction of vitamin inclusion levels in Salmonid diets should be done carefully.

**Introduction**

Global aquaculture production has surpassed capture fisheries, reaching 111 million tonnes in 2022, with projections to continue growing. This expansion raises concerns over fish welfare, particularly in relation to humane stunning and slaughter methods. The EU has established directives emphasising the minimization of suffering, especially during slaughter. While methods like electrical and mechanical stunning are deemed humane, practices such as ice asphyxiation and $CO_2$ exposure are considered inhumane. Despite increased awareness, many fish, including gilthead seabream, are still slaughtered without stunning, resulting in significant stress and muscle deterioration. This study investigates the effects of different stunning and slaughter techniques (electrical stunning, anaesthesia, and no stunning) followed by either ice-slurry or *ikejime* on the welfare and meat quality of gilthead seabream.

**Materials and Methods**

Conducted at the Estação Piloto de Piscicultura de Olhão (EPPO) in Portugal, this study involved 32 adult gilthead seabream. Fish were housed in three controlled outdoor tanks and acclimatized for 7 days before bio-loggers were surgically implanted to monitor heart rate and internal temperature. After a recovery period, the fish were subjected to various stunning and slaughter treatments: electrical stunning, anaesthesia, or no stunning, followed by either ice-slurry or *ikejime*. Physiological and behavioural data, including heart rate, blood samples, and muscle quality parameters, were collected. Data were analysed using linear mixed models (LMM) for heart rate, internal temperature and blood parameters, one-way ANOVA for muscle quality, and PCA for muscle quality and plasma datasets.

**Results**

We found notable differences in fish behaviour, heart rate, physiological responses, and muscle quality based on the stunning/slaughter method employed. Electrical stunning led to an immediate loss of visual consciousness, except for one fish that retained its vestibulo-ocular reflex (VOR). Fish slaughter with ice-slurry showed delayed loss of movement and more stress indicators, as well as significantly lower heart rates compared to those slaughtered with *ikejime*. Cortisol levels were highest in fish slaughtered by ice-slurry without prior stunning, indicating greater stress. Glucose levels were elevated in most treatments, with the highest increase seen in fish subjected to anaesthesia followed by *ikejime*. Other physiological markers, such as lactate, calcium, and potassium levels, varied significantly with the treatment. Electrical stunning followed by *ikejime* resulted in higher lactate and potassium levels. Muscle quality analyses showed that fish slaughtered only with *ikejime* or previously stunned with anaesthesia had softer, less chewy, and more water-retentive muscle than fish slaughtered with ice-slurry or electrically stunned. These two later groups also resulted in greater water and fat loss than the fish anaesthetised before slaughter.

*(Continued on next page)*

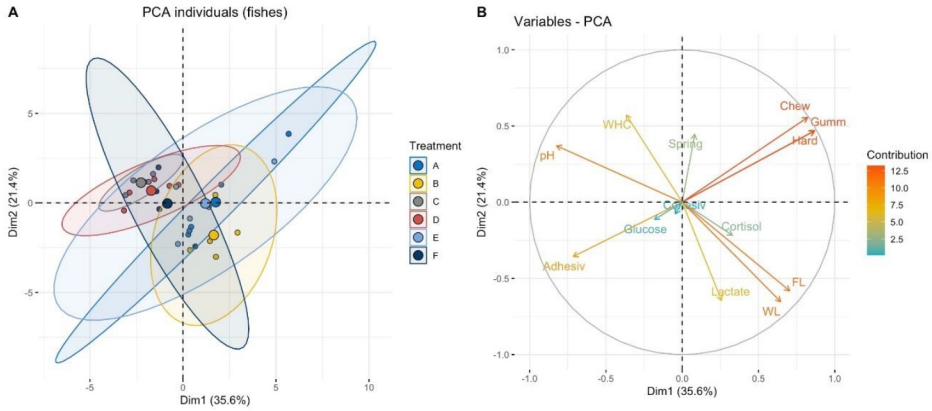

*Figure 1. PCA plots of individuals (left) and variables (right) of muscle considering the muscle quality data. PCA plot of individuals: the 95% confidence ellipses group fishes according to treatment. PCA plot of variables: The larger the value of the contribution, the more the variable contributes to the component. Treatments are: A. e- stunning + ice-slurry, B. e-stunning + ikejime, C. no stunning + ice-slurry, D. no stunning + ikejime, E. anaesthesia + ice-slurry, F. anaesthesia + ikejime.*

## Discussion

This study demonstrates that different slaughter techniques significantly impact both the physiological stress responses and muscle quality of gilthead seabream. Fish that were not stunned experienced prolonged consciousness and stress, particularly when slaughtered in ice-slurry, where they remained conscious for up to 18 minutes. Although anaesthesia and electrical stunning resulted in some unconsciousness, fish still showed stress responses during slaughter with ice-slurry, suggesting that these methods may not always be fully effective when in combination with ice-slurry. Ice-slurry induced bradycardia and higher cortisol levels, with unstunned fish exhibiting a faster temperature drop and greater stress. Muscle quality was best preserved in fish stunned with anaesthesia before slaughter, while electrical stunning led to lower pH and undesirable texture. In conclusion, while anaesthesia and *ikejime* produced the best outcomes for fish welfare and meat quality, electrical stunning requires further validation, and the development of automated *ikejime* could offer a humane and effective alternative for the industry.

# A MULTIBIOTIC COMPOUND FROM MACROALGAE IN PLANT-BASED DIETS MODULATES GUT INTEGRITY AND PUTATIVE PEPTIDE TRANSPORT IN *Sparus aurata*

**Introduction**

Several studies have shown that both microalgae and macroalgae offer significant nutritional benefits by helping prevent diseases and infections, due to their high content of vitamins, minerals, and essential fatty acids (Idenyi *et al*., 2022; Chandrasekar *et al*., 2024). These organisms have gained attention as promising natural sources for the development of nutraceutical products. One of the current challenges in aquaculture is determining whether such nutraceuticals can improve the performance of feed formulations with a high proportion of plant-based protein, particularly in commercially important species (Caderno *et al*., 2025). If successful, this approach could make aquaculture a much more environmentally sustainable economic activity. This study aims to evaluate the effects of Prebiodo II supplementation on intestinal structure and function in the context of a low-fishmeal diet, by analysing the expression of key genes in the anterior and mid-intestine of gilthead seabream (*Sparus aurata*).

**Materials and methods**

A total of 180 juvenile gilthead seabream (initial body mass: 54.58 ± 0.05 g) were randomly distributed into nine 300-L tanks (n = 20 fish per tank). Three experimental groups were established in triplicate and fed as follows: (i) a control diet containing a medium fishmeal level (12%); or the same basal formulation supplemented with either (ii) 1% or (iii) 3.5% of the nutraceutical compound Prebiodo II. Prebiodo II is a natural symbiotic nutraceutical based on macroalgae hydrolysates, alginate, and enzymatic-bacterial extracts, produced by Biotechnology Biopolym S.A. (Granada, Spain). Fish were fed *ad libitum*, with two meals per day, over a 91-day experimental period. The expression of several genes related to intestinal integrity, peptide transport, and immune response was examined in both the anterior and mid-intestinal segments.

**Results**

Similar gene expression patterns were observed across intestinal regions for the genes studied, which are involved in maintaining intestinal integrity, peptide transport, and immune function. In the anterior intestine (AI), gene expression remained stable among experimental groups, suggesting that this region maintains homeostasis despite dietary changes and supplementation with Prebiodo II.

In contrast, the mid intestine (MI) exhibited a significant downregulation of key genes (*igm, tlr9, oclb, oclc, cld4, cld7b, alpi, slc15a1, slc15a2,* and *slc15a4*) in the B1% group, whereas expression levels in the Control and B3.5% groups remained comparable (Fig. 1). This coordinated reduction may reflect a compromised intestinal barrier, impaired digestive and absorptive capacity, and weakened mucosal immunity. Specifically, the decreased expression of tight junction proteins (occludins and claudins) suggests increased intestinal permeability, while the downregulation of peptide transporters and immune markers may indicate deficits in nutrient uptake and local immune defense.

These findings suggest that Prebiodo II supplementation at a 1% inclusion rate negatively affects intestinal health in the mid-intestine, despite the absence of detrimental effects on growth performance and somatic indices at any tested level. Further investigation is warranted to elucidate the molecular mechanisms underlying this apparent dose-dependent response and to determine its potential long-term implications.

*(Continued on next page)*

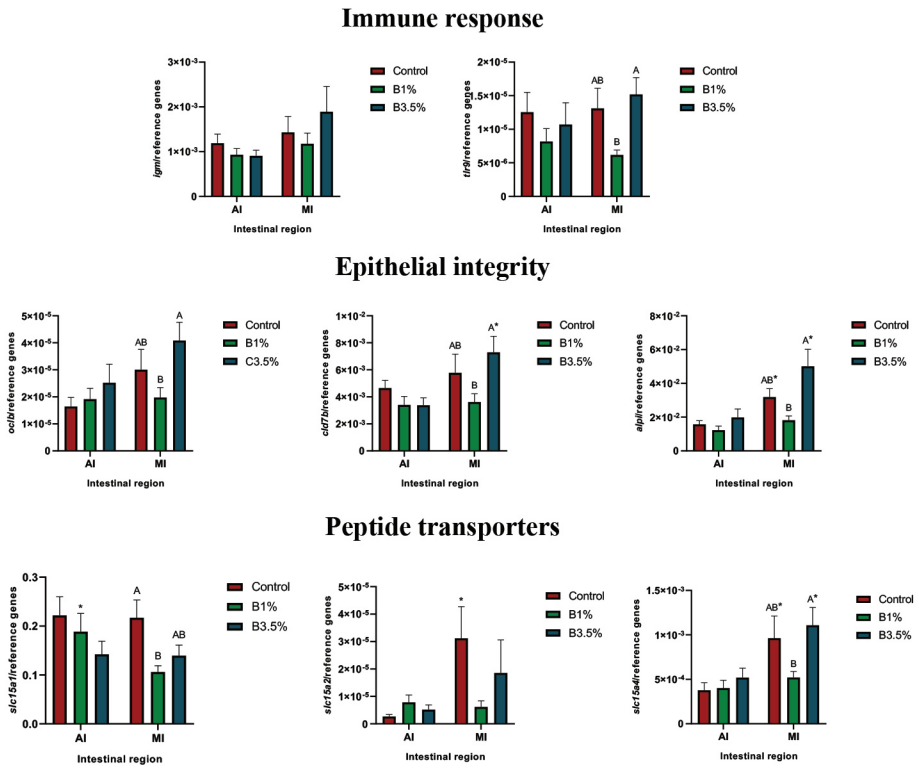

**Fig. 1.** Gene expression levels of *igm*, *tlr9*, *oclb*, *cld7b*, *alpi*, *slc15a1*, *slc15a2*, and *slc15a4* in the anterior (AI) and mid (MI) intestine of *Sparus aurata* fed different experimental diets (Control, B1%, and B3.5%). Data are expressed as mean ± SEM (n = 12 fish per experimental group). Different superscript letters indicate statistically significant differences among dietary treatments, while asterisks denote significant differences between intestinal regions within the same dietary treatment, as determined by two-way ANOVA followed by Tukey's post hoc test ($p < 0.05$).

# A DETERMINISTIC COMPARTMENTAL MODEL FOR FLAVOBACTERIOSIS CONTROL IN RAINBOW TROUT FARMING: FROM EPIDEMIOLOGICAL INSIGHTS TO MANAGEMENT AND GENETIC SELECTION STRATEGIES

Auguste Caen*[1] and Florence Phocas[1]

**Statement of the Problem**

Flavobacteriosis, caused by *Flavobacterium psychrophilum*, is a major threat to rainbow trout (*Oncorhynchus mykiss*) aquaculture, with outbreaks causing up to 70% mortality [1]. Current control strategies are limited, and understanding the epidemiological drivers—such as pathogen excretion, transmission efficiency, and environmental factors—is crucial for effective intervention. While existing studies focus on resistance through challenge experiments, few have developed comprehensive epidemiological models. Agent-based approaches, like that of Brenden et al.[2], provide simulations but lack analytical insights. To address this, we propose a deterministic compartmental model that enables both numerical and analytical examination of flavobacteriosis dynamics. This model offers practical guidance for managing aquaculture parameters during outbreaks and identifies key targets for genetic selection, advancing disease control strategies.

**Modeling Approach**

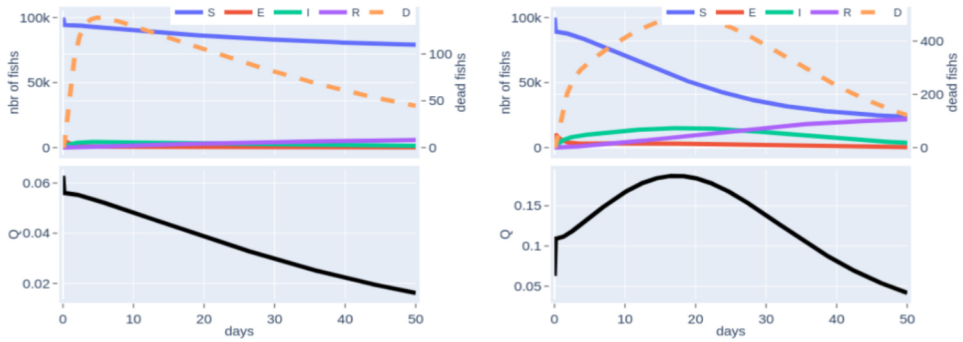
Our model follows a SIR-type framework [3]. It represents fish populations through compartmental states: susceptible ($S$), exposed but non-excreting ($E$), infected ($I$) and excreting (at rate $\beta_{I\to P}$), recovered and immune ($R$), and dead ($D$) but still excreting (at rate $\beta_{D\to P}$). The pathogen concentration in the system ($P$) is reduced by water outflow at rate $\gamma$. Epidemiological parameters $\beta$ govern transitions between states, while the mortality removal frequency and the water exchange $\gamma$ are aquaculture-specific factors. The full system is formalized in Equation (1).

$$\dot{S} = -\beta_{S\to E}PS \qquad \dot{R} = \beta_{I\to R}I$$
$$\dot{E} = \beta_{S\to E}PS - \beta_{E\to I}E \qquad \dot{D} = \beta_{I\to D}I - \mu D$$
$$\dot{I} = \beta_{E\to I}E - (\beta_{I\to R} + \beta_{I\to D})I \qquad \dot{P} = \beta_{I\to P}I + \beta_{D\to P}D - \gamma P$$

**Epidemic Intensity and Control**

We analytically demonstrate that epidemics always extinguish, with a subset of fish remaining uninfected. We pinpoint both farm management strategies -- such as increasing the water outflow $\gamma$ -- and critical epidemiological traits -- such as recovery rate ($\beta_{I\to R}$) and pathogen excretion rate ($\beta_{I\to P}$) -- as targets for genetic selection, aiming to optimize disease resilience in farmed populations. However, the mortality rate ($\beta_{I\to D}$) requires careful consideration: it should be maximized if $\frac{\beta_{I\to P}}{\beta_{I\to R}} > \frac{\beta_{D\to P}}{\mu}$ (prioritizing rapid removal of infected fish) or minimized otherwise (reducing overall mortality). We introduce an epidemic intensity indicator, Q=E+I+a D+ bC, where a>0 and b>0 are positive scalars dependent on model parameters. Q equals zero if and only if the epidemic is extinct. Our analysis reveals that Q exhibits only two possible behaviors: it either **rises and then declines to zero** (indicating an epidemic that takes hold before fading) or **declines immediately to zero** (indicating an epidemic that fails to establish itself). Through analytical study, we derive a critical threshold for epidemic growth: the epidemic spreads if and only if$\zeta = \frac{\gamma\mu}{\beta_{S\to E}} \frac{\beta_{I\to R}+\beta_{I\to D}}{\beta_{D\to C}\beta_{I\to D}+\mu\beta_{I\to C}} < 1$This result provides a clear target for intervention: parameters must be adjusted until $\zeta > 1$ to contain the epidemic.

*(Continued on next page)*



(a) $\zeta > 1$ (b) $\zeta < 1$

*Fig 1.* For each simulation, the upper panel shows the proportion of fish in each compartment (susceptible, exposed, infected, recovered, and dead) within the aquaculture system, while the lower panel depicts the epidemic intensity indicator Q. Panel **(a)** corresponds to $\zeta > 1$ , where Q declines immediately, indicating an epidemic that fails to establish. Panel **(b)** corresponds to $\zeta < 1$ , where Q initially increases before decaying to zero, reflecting an epidemic that takes hold before subsiding.

**Model Calibration and Simulation**

Calibrating this model is challenging due to the lack of comprehensive monitoring data from aquaculture systems. While existing infection experiments in the literature only allow analysis of specific epidemiological fluxes, we combined multiple datasets to calibrate the model and generate realistic simulations. Figure 1 illustrates two scenarios, corresponding to (epidemic growth) and (epidemic extinction).

**Introduction**

Marine farmed fish are praised for their nutritional value for human consumption, but their *n*-3 long-chain (≥C20) polyunsaturated fatty acids content strongly depends on their diet. For decades, fishmeal and fish oil have been used to formulate aquafeeds, a practice that is increasingly questioned, as it supplies *n*-3 LC-PUFA through fish for human consumption but also depletes wild fish resources. To tackle the generalised shortage of *n*-3 LC-PUFA rich marine ingredients, the industry started targeting plant-based ingredients. However, these are richer in *n*-6 fatty acids and lack *n*-3 LC-PUFA. These caveats negatively affect fish health, performance, and nutritional value.

The quest for the diversification of sources able to deliver suitable levels of *n*-3 LC-PUFA has focused on krill and single-cell organisms (e.g., microalgae and protists). However, most of such alternatives are still too costly for mainstream uses. Bio-engineered transgenic oilseed crops have also been put forward as an option, but their fatty acid profiles often feature an imbalanced *n*-3/*n*-6 ratio, and several countries still restrict the use of genetically modified organisms. Insects have sparked a growing interest in the industry, being considered as a promising ingredient for aquafeeds formulation, with emphasis on black soldier fly (*Hermetia illucens*). However, insects only display interesting levels of *n*-3 LC-PUFA if these are supplied through their diet, as they bioaccumulate these biomolecules, rather than biosynthesizing them *de novo*.

Marine gammarid amphipods emerge as a promising source of *n*-3 LC-PUFA, despite remaining largely overlooked. These highly diverse groups of "sea bugs", are in fact shrimp-like peracarid crustaceans (with a few mm size) that are found in multiple aquatic environments. Their trophic plasticity makes them promising candidates for circular bioeconomy approaches, aiming to add value to terrestrial food-processing by-products by upgrading them into a *n*-3 LC-PUFA rich biomass.

***n*-3 LC-PUFA profile of marine gammarids**

The ability of marine gammarids to produce *n*-3 LC-PUFA has been reasoned from feeding experiments studying the impact of different diets on the fatty acids of their body composition. While gammarids possess elongases that play a role in *n*-3 LC-PUFA biosynthesis, the full mechanism of eicosapentaenoic acid (EPA, 20:5*n*-3) and docosahexaenoic acid (DHA, 22:6*n*-3) synthesis is yet to be fully understood on these organisms, as they appear to lack desaturases; these enzymes are needed for *de novo* synthesis of these fatty acids through known pathways. It has been hypothesized that this ability to synthetize EPA and DHA may result from alternative mechanisms, such as contributions from gammarids' microbiota. These "sea bugs", namely *Gammarus locusta* (Figure 1), have been shown to be able to perform trophic upgrade, as they can convert lower-value feeding substrates (e.g., seaweeds, land vegetables…) into higher-value nutrients, which ultimately improves their nutritional value as a dietary ingredient/supplement. By using diets from non-marine sources, namely agricultural by-products, to farm marine gammarid amphipods, one can support circular bioeconomy principles and enhance resource efficiency, while simultaneously reducing the needs on more traditional ingredients.

*(Continued on next page)*

**Conclusion**

Marine gammarid amphipods can convert both lower-value marine and non-marine feeding substrates into high-value *n*-3 LC-PUFA through trophic upgrade. With farmed amphipod gammarid offspring reaching sexual maturity at only six weeks post-hatching it may be possible to address nutritional programming and selective breeding practices, allowing to develop lineages that may even outperform wild conspecifics in terms of their *n*-3 LC-PUFA composition. Overall, this approach will strongly contribute to merge green and blue food ecosystems, contributing towards a more sustainable aquaculture.

# MICROBIAL INFLUENCE ON BLACK SPOT DEFECT IN FARMED SHRIMP: THE ROLE OF BIOFLOC SYSTEMS IN MITIGATION

## Introduction

Shrimps are one among the most traded species around the world. In the world, (*L. vannamei*) is the most desired species for cultivation owing to several advantages over other species (FAO, 2014). As in the case of any food product, spoilage in shrimps is a major concern for shrimp farmers and shrimp processing industry. The shrimp are a highly perishable product due to their rapid microbiological and biochemical spoilage post-harvest. Black spot (melanosis) is a common post-harvest defect in farmed shrimp, characterized by dark pigmentation on the shell due to enzymatic oxidation. In biofloc production systems, which enhance water quality and shrimp immunity through microbial floc, the occurrence of black spot may be influenced by factors such as water composition, stress during harvest, and microbial dynamics. While biofloc offer improved health and growth performance, their impact on post-harvest quality, including melanosis susceptibility, remains a critical area for optimization in commercial shrimp farming. The primary objective of this study is to evaluate the impact of microbial dynamics on the development of black spot disease in farmed shrimp during ice storage, while comparing different slaughter methods and investigating the potential of biofloc systems to mitigate the disease over time.

## Material and Methods

Four slaughter methods were evaluated: cold thermal shock (TS) using refrigerated seawater (-2ºC) (TREATMENT-2 -Control-) (TS was implemented in all slaughter methods); 5 min immersion in refrigerated seawater (0±2.5 ºC) with 50 ppm bleach followed by TS (TREATMENT-1); clarification (3–4 h) before 50 ppm bleach (TREATMENT-3) and TS; and TS followed by 2 min UV exposure in each side of the shrimp (TREATMENT 4). A trained sensory assessor's panel evaluated the melanosis progression, over 7 days on interval of 48 h, using the procedure "Melanosis Score Sheet" described in Montero et al (2001). Additionally, bacterial specific study (Specific Spoilage Organism -SSO-, Total Viable Count -TVC-, Pseudomonas -PSE-, Enterobacteria -ET- and Psychotropics -PST-) was carried out, together with a physicochemical parameter (non-protein nitrogen-TVB-N). The data collected were analysed using XLSTAT® statistical software, performing descriptive analysis, panel analysis, ANOVA and Fisher's post hoc tests. The results were presented using a Principal Component Analysis (PCA) as a general test.

## Results and discussion

The PCA analysis (Fig.1) of fresh shrimp stored on ice reveals critical insights into spoilage progression and the effectiveness of four different treatments. Microbiological indicators such as Specific Spoilage Organisms (SSO), Pseudomonas (PSE), and Total Viable Count (TVC) are closely grouped on the left side of the plot, correlating with early spoilage and associating with samples from DAY-0 and DAY-3. These early-stage samples also align with TREATMENT-1 and TREATMENT-2, suggesting these treatments are effective at preserving microbial quality in the initial storage period. In contrast, spoilage parameters like Enterobacter (ET), Psychrotrophics (PSY), Total Volatile Basic Nitrogen (TVBN), and black spot development point toward the right and lower quadrants of the plot, indicating their relevance in advanced spoilage. DAY-9 and especially DAY-12 are positioned along these spoilage vectors, highlighting a significant decline in quality over time. Notably, TREATMENT-3 clusters near DAY-12 and the black spot vector, indicating it was the least effective in controlling spoilage and melanosis. TREATMENT-4 shows moderate performance, with some overlap toward spoilage indicators. Overall, this analysis shows that TREATMENTS 1 and 2 provide the best preservation of shrimp quality, particularly within the first nine days of storage, while TREATMENT-3 fails to mitigate spoilage effectively.

*(Continued on next page)*

**Conclusions**

The study clearly demonstrates the critical influence of slaughter methods on the microbiological quality and shelf-life stability of ice-stored shrimp, from biofloc production system with melanosis (black spot) emerging as a key quality-degrading factor impacting commercial value. Among the evaluated approaches, TREATMENT-1—involving immersion in refrigerated seawater (0 ± 2.5 ºC) with 50 ppm sodium hypochlorite followed by cold thermal shock (TS)—proved the most effective, showing strong correlations with suppressed microbial loads (TVC, SSO, PSY), lower TVBN levels, and significantly delayed black spot development, particularly up to DAY-9. TREATMENT-2 (TS alone, used as control) also maintained acceptable microbial quality but was slightly less effective in controlling melanosis, which can negatively affect consumer acceptance and marketability. In contrast, TREATMENT-3 (clarification followed by bleach and TS) resulted in elevated spoilage indicators and pronounced black spot formation by DAY-12, rendering it commercially unviable. TREATMENT-4 (TS followed by UV exposure) showed intermediate performance, with no substantial advantage over the control. From a commercial perspective, TREATMENT-1 is strongly recommended for ice-storage operations targeting extended shelf life and high sensory quality, particularly for export markets where appearance is critical. It is further recommended that shrimp be marketed or processed by DAY-6 to DAY-9, and that regular monitoring of melanosis and microbial indices be implemented to ensure product integrity, reduce losses, and meet regulatory and customer expectations.

**Introduction**

Fibroblast growth factor 21 (FGF21) belongs to the endocrine FGF subfamily and is widely recognised in mammals as a metabolic regulator crucial for energy balance. It is mainly expressed in hepatic tissues across most species, where its expression is increased under fasting conditions. Among other functions, FGF21 promotes gluconeogenesis, ketogenesis and fatty acid oxidation (1). Furthermore, it has been observed that diets rich in carbohydrates and low in protein increase FGF21 levels, promoting protein intake and influencing food preferences. These responses are mediated centrally by FGF21, which acts as a key hormone signalling protein restriction in the brain, particularly by increasing the reward value of protein-containing foods through dopamine-related neural circuits (2)cost, and nutritional value can vary markedly. Animals have thus developed neural mechanisms that enable the detection of nutrient restriction, and these mechanisms engage adaptive physiological and behavioral responses that limit or reverse this nutrient restriction. This review focuses specifically on dietary protein as an essential and independently defended nutrient. Adequate protein intake is required for life, and ample evidence exists to support an active defense of protein that involves behavioral changes in food intake, food preference, and food motivation, likely mediated by neural changes that increase the reward value of protein foods. Available evidence also suggests that the circulating hormone fibroblast growth factor 21 (FGF21.

This information offers valuable insights that can be extrapolated to improve aquaculture feeding research, emphasising the importance of understanding and modulating the nutritional and sensory cues that drive fish feeding behaviour. Specifically, understanding the role of Fgf21 and reward pathways in regulating protein-specific appetite could lead to the development of optimized feed formulations that align with the animals' natural adaptive mechanisms for detecting and responding to protein deficiency. However, very little information is available on Fgf21 in fish. Only two studies address the metabolic role of this protein and its relation with feed intake regulation: one in zebrafish (*Danio rerio*) (3), which found that Fgf21 plays an orexigenic role and is modulated by feeding state, exerting a significant influence on glucose and lipid metabolism; and the other in Asian seabass (*Lates calcarifer*) (4)whereas potential functions of this gene in teleosts are still unknown. We identified the Fgf21 gene and studied its functions in Asian seabass (Lates calcarifer, which revealed several differences compared to the mammalian model, including a different expression pattern, fasting-induced downregulation and an anorexigenic role of Fgf21. These interspecies differences in fish, as well as differences with mammals, led us to conduct the present experiment. Using rainbow trout (*Oncorhynchus mykiss*) as a model of high economic value in aquaculture, we outline a study to characterise the metabolic role of Fgf21 and its effect on feed intake, from molecular characterisation to physiological response.

**Materials and methods**

Juvenile rainbow trout were acclimated to standard conditions: temperature (15ºC ± 1ºC), photoperiod (12 h light:12 h dark), and feeding (once daily at 10:00 h with commercial dry pellets, hand-fed until apparent satiety). Fish were maintained in 100 L tanks with aerated, dechlorinated tap water in an open recirculating system. For the tissue distribution analysis, 6 randomly selected fish were fasted for 48 h, sacrificed, and various tissues were collected. Total RNA was then extracted to quantify relative *fgf21* mRNA levels by RT-qPCR. Additionally, to examine the daily profile of *fgf21* mRNA abundance in the hypothalamus, a second group of 42 animals maintained under standard conditions was sampled every 4 hours throughout the light/dark cycle (n = 6 per sampling point), starting at ZT0 (lights on), and continuing at ZT4, ZT8, ZT12 (lights off), ZT16, ZT20, and ZT24 of the following day. Primers for *fgf21* were previously designed using Primer designing tool from NCBI, and their specificity and effectiveness were validated. Daily rhythms of gene expression were assessed by fitting a single cosine function to the relative mRNA abundance values across the seven time points using the Cosinor.Online application.

*(Continued on next page)*

In a second experiment, fish were individually weighted and distributed in 3 tanks (n = 13 / tank). During the acclimatation period, fish were fed twice daily, and basal levels of feed intake were recorded. On the day of the experiment, animals were intraperitoneal (IP) administered with one of the three treatments: saline solution alone (control) or containing either 100 ng/g or 200 ng/g of recombinant Fgf21. Feed intake was recorded at 2, 8, 26, 32, 50, 56 h post-administration. The experiment was repeated four times, replacing the animals in each replicate. Finally, a fifth replicate was performed to collect tissue samples at 2 and 8 h post-administration. Fish were sacrificed and samples of liver, adipose tissue, and hypothalamus were collected for qPCR analysis of various genes related to feed intake regulation and metabolism. For statistical analysis, a two-way ANOVA was conducted using RStudio 2024.12.1, considering treatment (control, 100 ng/g, and 200 ng/g Fgf21) and time (2 h and 8 h) as main factors. When significant effects or interactions were detected ($p < 0.05$), post-hoc Tukey's multiple comparisons tests were performed.

**Results and discussion**

Analysis of gene encoding Fgf21 distribution in rainbow trout revealed a generally higher expression in central regions compared to peripheral tissues. Notably, unlike in mammals, no expression was detected in the liver of rainbow trout, a pattern also reported in Asian seabass (4)whereas potential functions of this gene in teleosts are still unknown. We identified the Fgf21 gene and studied its functions in Asian seabass (Lates calcarifer, supporting the idea that Fgf21 functions differ between fish and mammals. Furthermore, hypothalamic mRNA abundance of *fgf21* displayed clear daily oscillations, peaking around the beginning of the dark phase (ZT12). This pattern suggests that Fgf21 may be involved in the circadian regulation of metabolism or feeding behaviour.

The IP administration of recombinant Fgf21 in rainbow trout resulted in a reduction of feed intake, which was more pronounced at 2, 8, and 26 h post-administration of the high dose. This anorexigenic response is consistent with findings previously reported in Asian seabass (4)whereas potential functions of this gene in teleosts are still unknown. We identified the Fgf21 gene and studied its functions in Asian seabass (Lates calcarifer. In the hypothalamus, Fgf21 increased *cartpt* and *pomca1* mRNA levels, particularly at 8 h post-injection, suggesting activation of anorexigenic pathways consistent with the observed reduction in feed intake. In parallel, *ampkα2* was also upregulated at 8 h with the high dose, indicating activation of central energy sensing mechanisms. Furthermore, there was a non-significant trend towards increased levels of *fgf21* and its receptor *fgfr1a2*, which suggests a potential enhancement in central sensitivity to Fgf21. In the liver, Fgf21 induced a lipid catabolism shift, upregulating *pparα* and *cd36* while downregulating *glut2* and *fbp*. Additionally, *ampkα1* increased and *mtor* decreased, reflecting activation of energy-saving mechanisms consistent with the central response. In adipose tissue, Fgf21 promoted a time-dependent regulation of lipid metabolism, with early activation of *hadh* (2 h) and later induction of *cpt1b* (8 h). Lipogenesis was suppressed by the high dose of Fgf21 via downregulation of *srebp1c* and *lxrα*, while *pfk* and *fbp* also decreased, indicating reduced glucose use and a switch to lipids as preferred energy source.

Overall, these findings suggest that Fgf21 plays a key role in the regulation of energy balance, feeding behaviour, and lipid metabolism in rainbow trout. The distinct tissue distribution, daily oscillations in hypothalamic expression, and the metabolic and anorexigenic responses to exogenous Fgf21 administration highlight functional differences between fish and mammals and point to a species-specific role of Fgf21 in coordinating central and peripheral energy homeostasis.

## Introduction

Organic pollutants (OPs) of anthropogenic origin are widespread in surface water globally including pharmaceuticals and personal care products (PPCPs), per- and polyfluoroalkl substances (PFASs), pesticides, microplastics (MPs), and so on. In this study, the European eel (*Anguilla Anguilla Linnaeus*, 1758) was selected to study the bioconcentration of OPs, given its physiological and behavioural characteristics, which make it vulnerable and sensitive to the presence of these substances (1). Furthermore, in 2007, it was placed on the International Union for Conservation of Nature's Red List of Endangered Species, listed as "critically endangered" (2). Overfishing, water barriers hindering migration, climate change, parasitic diseases, habitat reduction and chemical pollution, among others, can be defined as main causes of the drastic reduction of its population since 1970 (1). The general aim of this research was to study the bioconcentration and depuration kinetics of a mixture of 22 OPs in muscle, liver tissue and plasma of European eel, and to evaluate the influence of MPs in them.

## Materials and methods

The OPs included 10 PPCPs, 5 pesticides, 5 PFASs and 2 illicit drugs, which were vehiculated through water or food, depending on their chemical properties. The compounds of the former group are acetaminophen, atenolol, bentazone, bufotenine, caffeine, diclofenac, etoricoxib, ibuprofen, imazalil, naproxen, perfluorobutane sulfonate (PFBS), perfluorodecanoic acid (PFDA), perfluorooctane sulfonate (PFOS), perfluorooctanoic acid (PFOA), perfluoropentanoic acid (PFPeA), salicylic acid, terbuthylazine, and vildagliptin (n=18). The compounds that were supplied through food include (n=4): chlorfenvinphos, chlorpyrifos, triclosan and 4-methoxyphencyclidine (4-MeO-PCP). The experimental study lasted 58 days including: (a) an exposure stage (days 0-28), in which the mixture of OPs and spherical MPs (polyethylene) was administered through water (10 µg/L of OPs and 0.04 g MPs per specimen), and through food (20 ng per eel/day); and (b) a depuration phase (days 29-58), in which the water from aquariums was renewed (without OPs). OPs in eels' muscle and liver samples were extracted by QuEChERS and dispersive solid phase extraction (dSPE) whereas plasma was extracted by SPE (3). Extracts were analysed via UHPLC-MS/MS. The average weight and lengths of the silver (adult) European eels (n=144) employed were 63.3±18.3 g and 30.8±3.1 cm.

## Results and discussion

The exposure through water of diclofenac, etoricoxib, imazalil, PFDA, PFOA, PFOS, terbuthylazine, and through food of chlorpyrifos, at the tested concentrations, seemed to cause their bioconcentration in the three eels' tissues (with and without MPs). Other pollutants appeared to show a preferential tissue bioconcentration as caffeine, chlorfenvinphos (muscle), naproxen (liver), bufotenine and PFBS (plasma), triclosan (muscle, liver), and 4-MeO-PCP (liver, plasma). During the exposure stage, two different trends were observed. A first group of OPs with increasing concentrations in the three tissues (PFDA, PFOS, PFOA, chlorpyrifos, and terbuthylazine), or in some of them, and a second group with less clear or erratic trends. PFASs concentrations followed the trend plasma > liver tissue > muscle. The occurrence of MPs seemed to play an important role in the bioconcentration kinetic of the OPs analysed here. Some recent research have proved that MPs can act as vectors of pollutants in the aqueous environment (4). During the depuration stage, the OPs described two trends. In the first one, concentrations tended to decrease (chlorpyrifos, terbuthylazine), and in the second one, concentrations were similar or even tended to be higher than were those measured at the exposure phase (PFDA, PFOS, PFOA). In relation to the occurrence of MPs, concentrations reached at the end of the depuration phase tended to be higher at the group with MPs than at group without them in muscle and liver tissue, but lower in the group without them (plasma).

*(Continued on next page)*

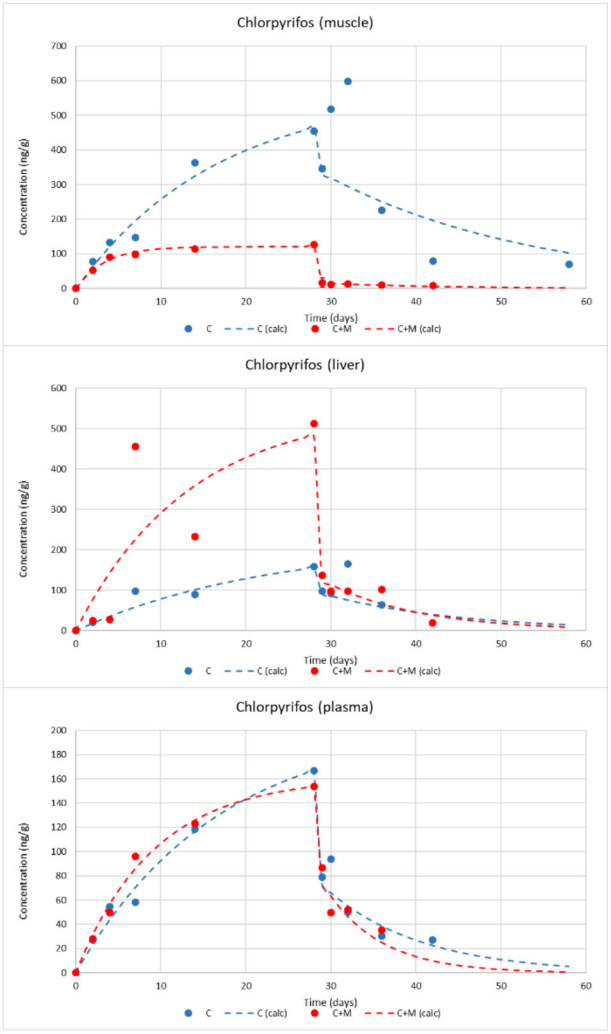

**Fig 1.** Toxico-kinetic curves from the modelling in both groups (C: OPs, C+M: OPs + MPs) for chlorpyrifos.

## Conclusions

Many pollutants are widespread and measured concentrations are at a level that more than likely is causing ecotoxicological effects in European eels. Legacy substances such as PCBs and heavy metals are relatively well studied, however the impact on the eel of emerging compounds (e.g. PPCPs, PFASs, illicit drugs, etc.) which are known to pose serious and increasing problems in aquatic ecosystems, is poorly understood. Compared to other fish species, eels are challenging to study and to protect due to their catadromous and semelparous lifecycle. We have proved that pollutants are not distributed evenly among eels' tissues and that higher concentrations can be found in plasma and liver than in muscle. Bioconcentration and depuration of OPs in eels seemed to be highly determined by the type of pollutant, and by different processes related to the combination of a mixture of chemicals including the presence of MPs. Further research is needed to clearly understand the effects and toxicity, singly and cumulatively, of multiple and different pollutants in target organs of (wild) eels, and to assess their partitioning and distribution among eel tissues.

**Introduction**

Transposable elements (TEs), better known as transposons or "jumping genes", are dispersed, repetitive DNA segments able to move and insert autonomously in the genome through copy-and-paste RNA (class I retrotransposons) or cut-and-paste DNA mechanisms (class II transposons) (Finnegan, 1989). TEs account for most of the vertebrate genome and, although long dismissed as "junk DNA", they have fuelled events such as speciation, de-novo gene birth and large-scale chromosomal rearrangements (Auvinet et al., 2018; Long et al., 2003; Lönnig & Saedler, 2002). However, uncontrolled mobilisation of TEs can compromise genome integrity, and trigger chronic inflammation or even tumourigenesis through persistent activation of transcription factors such as NF-κB and p53 (Gudkov et al., 2011). In this sense, epigenetic locks such as methylation and acetylation are able to keep TEs silent (Saul & Kosinsky, 2021). In addition, the immune system is able to operate as a second surveillance mechanism whereby, when epigenetic silencing fails, TE-derived nucleic acids accumulate in the cytoplasm. Then, they are able to mimic viral signatures and activate canonical DNA/RNA sensors such as Toll-like receptors, triggering type I interferon and pro-inflammatory cytokine responses that restrain further mobilisation (Rakoff-Nahoum & Medzhitov, 2009). In this context, teleost fishes are particularly noteworthy for harbouring the largest repertoire of TEs known to date, while possessing the earliest and most fully developed combination of innate and adaptive immune defences among vertebrates (Swain & Nayak, 2009). Nevertheless, the critical relationship between TEs and immune system, potentially central to understanding TE activity and its consequences, remains largely unexplored in fish species.

**Material and Methods**

Canonical TEs consensus sequences for eight cultured teleosts—zebrafish (*Danio rerio*), green pufferfish (*Tetraodon nigroviridis*), Japanese medaka (*Oryzias latipes*), European seabass (*Dicentrarchus labrax*), rainbow trout (*Oncorhynchus mykiss*), European eel (*Anguilla anguilla*), Nile tilapia (*Oreochromis niloticus*) and gilthead seabream (*Sparus aurata*)—were retrieved from FishTEDB. Each species-specific library was imported into OmicsBox software (v. 3.4.5) and launched as a BLASTn query (E-value $\leq 1 \times 10^{-10}$) against the full Actinopterygii section of GenBank. The resulting hit tables were inspected manually, and for every TE, we flagged alignments whose first (highest-scoring, longest) match overlapped a locus annotated as immune-related (e.g., *tlr*, *nlr*, *ifn*, complement, cytokine, antiviral genes, etc.) and discarded the rest to avoid redundancies produced by long consensus sequences. For each retained TE-immune pair we recorded TE class/superfamily, alignment coverage (% query length) and identity; matched immune gene names were cross-checked in UniProt to confirm their immune function. Curated lists were then collated by species to expose shared versus lineage-specific patterns.

**Results and Discussion**

The screen yielded 333 robust TE–immune contacts distributed among the eight species. Most insertions clustered in membrane-bound pathogen-recognition receptors (Toll-like, complement and assorted cytokine receptors), cytosolic inflammasome sensors of the NLR-PYD/CARD family, and antiviral effectors such as type-I interferons, and Mx proteins. hAT, Tc1-Mariner, and L2- and L1-type LINEs lineages dominated, underscoring repeated involvement of both DNA-transposon and retrotransposon and classes in shaping immune loci. Based on these results, we hypothesize that TE fragments persisting in regulatory or coding regions of membrane receptors could have been selectively retained whenever they conferred improved pathogen detection or signalling capacity, thereby driving the expansion and functional diversification of innate-immune receptors in fish (Krasnov et al., 2005). Incomplete insertions—such as the TE fragment within *tlr9* of rainbow trout—could likewise function as inducible regulatory modules, adding an extra layer of epigenetic control (Ortega-Villaizan et al., 2009). Altogether, the observed pattern could be consistent with a scenario in which TE-driven genetic variation helps teleosts adapt to pathogen-rich aquatic habitats.

*(Continued on next page)*

In conclusion, this multi-species *in-silico* survey uncovers a widespread presence of TE across key innate-immune pathways of eight farmed teleosts, underlining mobile DNA as a silent architect of fish immune evolution. Therefore, our results offer a new insight into the relationship between ET and the immune system that may be key to the search for genomic markers and the development of new vaccines in aquaculture.

# ADVANCE YOUR RESEARCH THROUGH AQUASERV

Adelino V. M. Canario* and Ana Aranda Silva

Centro de Ciências do Mar do Algarve
Universidade do Algarve
Faro, Portugal
e-mail: aquaserv@ualg.pt

AQUASERV (aquaserv-ri.eu) is a research infrastructure (RI) project funded by Horizon Europe that offers access to scientific services in over 60 European facilities related to Aquaculture, Fisheries, Ecosystem Restoration, and the Blue Economy.

AQUASERV aims to significantly further scientific advances and promote and facilitate the implementation of the European Common Fisheries Policy, the Farm to Fork Strategy, the Sustainable Blue Economy and the European Green Deal.

AQUASERV will achieve these objectives by offering scientists from academia and business remote and on-site transnational (TA) and virtual (VA) access to an advanced set of European research infrastructures and their nodes related to research and management of marine and freshwater biological resources, food and biotechnology. These include the European Marine Biological Resource Centre (EMBRC ERIC), the Analysis and Experimentation on Ecosystems (AnaEE ERIC), the Aquaculture for Excellence for Aquaculture in Fish (AQUAEXCEL), the Infrastructure for Promoting Metrology in Food and Nutrition (METROFOOD), and the International Council for Exploration of the Sea. It also includes the Research Infrastructure for Science and Innovation Policy Studies (RISIS) to bring contributions from the social sciences, and the European Society for Aquaculture (EAS).

Detailed information on how to benefit from AQUSERV will be provided.

Acknowledgement: Funded by the European Union

# THE SUITABILITY OF THE GUADALQUIVIR ESTUARY TO DRIVE THE REHABILITATION OF DRAINED MARSHES AND ACCESS NEW NET SOURCES OF AQUATIC FOOD

Ana Prieto, Catalina Fernández-Díaz, Cesar Vílas, Jose-Pedro Cañavate*

IFAPA Centro El Toruño

**Introduction**

The Guadalquivir marshes (SW Spain) have been the subject of a vast transformation for agricultural purposes since the 1940s, affecting ~75% of their original surface area of around 2,000 km$^2$. The affected areas were hydrologically disconnected from the estuary, which has also been adapted as a navigation channel, showing high turbidity, low chlorophyll content, and a high nutrient load. A significant fraction of the transformed marsh, particularly on the left bank of the estuary, remains uncultivated. Recently, initiatives have been undertaken to reconnect some of these uncultivated areas of the marsh with the estuary. Within this context, a new situation arises in which a brackish, hypereutrophic estuarine environment is uninhibited in its light limitation when it enters shallow-water marshes. Controlling the residence time of these estuarine water bodies in marsh ponds allows for the development of significant primary productivity, which provides the trophic support for obtaining new aquatic food resources on a net basis. Thus, the goal of present study was to understand the potential for primary food production in marshes flooded with brackish water from a eutrophic estuary.

**Material and Methods**

The study was conducted in a 13.5-hectare rehabilitated marshland (36º53'34.41"N; 6º13'41.23"W), flooded with water from the Guadalquivir estuary. Water flows from those ponds (1.2 m depth) in this area used for extensive aquaculture to another bigger pond (0.5 m depth) that is managed to promote wildlife conservation. Nutrients ($NO_3^-$, $NO_2^-$, $NH_4^+$, $PO_4^{3-}$, $SiO_4^{4-}$) and chlorophyll a were determined for an annual cycle during the 2023-2024 biennium. The species composition of phytoplankton was also determined by microscopic observation. Sampling was monthly in the estuary and fortnightly in the marsh ponds. To determine primary production rates, dissolved oxygen and pH were recorded every 10 min. The autonomous HOBO U26-001 (oxygen) and HOBO MX2501 (pH) probes were used, which were replaced and recalibrated during the fortnightly sampling periods. The recorded dissolved oxygen series were integrated according to Needoba et al. (2012) to calculate the corresponding gross (GPP) and net primary production (NPP) rates. To determine GPP and NPP directly from daily changes in dissolved inorganic carbon (DIC), the thermodynamic dissociation constants of Millero (2010) were used for the specific conditions of total alkalinity, pH, salinity and temperature in the water.

**Results**

The main feature of the eutrophic nature of the Guadalquivir Estuary was its high nitrate concentration. It is interesting to note how, after flowing through the marsh ponds, the level of nitrate remaining in the water was negligible, while silicate, which also had a high concentration in the estuary, was only reduced by around 50% (Table 1). The significant ammonium increase in marsh waters (Table 1) is consistent with its increased metabolic activity. Around 35% of the relatively lower phosphate concentration in the estuary, that resulted in a high molar N/P ratio around 65, remained in marsh ponds (Table 1).

Salinity at the estuary water intake point ranged from 12.7 to 25.9. Chlorophyll a concentration increased from an average of 5.9±3.8 µg l$^{-1}$ in the estuary to 75.4±44.1 µg l$^{-1}$ in the marsh. The phytoplankton community in the marsh ponds was dominated by high nutritional value microalgae species of the haptophye (mainly *Diacronema* spp) and diatom groups (*Chaetoceros*, *Cylindrotheca*). Both GPP and NPP were highest in spring and summer, decreasing by approximately half in autumn and winter (Figure 1). NPP accounted for 63% or 50% of GPP when primary production was calculated according to changes in dissolved oxygen or DIC, respectively. Estimates based on DIC changes were lower than those based on oxygen evolution (Figure 1), indicating a significantly higher ($P<0.05$) photosynthetic quotient (PQ) in summer (PQ=1.84) than in the other seasons (PQ=1.27 in winter, PQ=1.31 in spring, PQ=1.47 in autumn).

*(Continued on next page)*

Table 1. Annual records for the mean and standard deviation of nitrate, nitrite, ammonium, phosphate and silicate concentrations (µM) in the Guadalquivir estuary and after flowing through the studied marsh ponds.

| | $NO_3^-$ | $NO_2^-$ | $NH_4^+$ | $PO_4^{3-}$ | $SiO_4^{4+}$ |
|---|---|---|---|---|---|
| Estuary | 131.7±56.1 | 1.1±1.1 | 1.8±1.9 | 2.0±0.7 | 70.6±64.2 |
| Marsh | 0.1±0.6 | 0.8±1.1 | 14.3±18.5 | 0.7±0.6 | 41.2±17.0 |

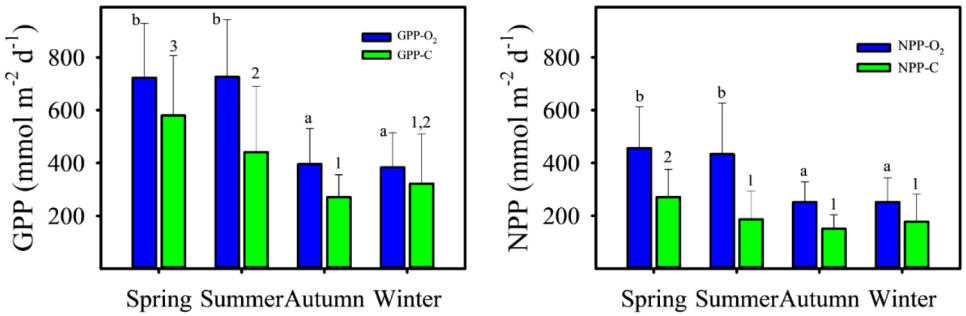

Figure 1. Seasonal gross (left graph) and net (right graph) primary production in marsh ponds flooded with Guadalquivir estuary waters. Same letters and numbers indicate homogeneous seasonal groups (Tukey test; $p<0.05$) based on dissolved oxygen or DIC evolution, respectively

In terms of net C, the average daily primary production for the annual cycle was 187±86 mmol C $m^{-2}$ $d^{-1}$. By integrating the daily NPP records for an annual cycle and transforming to units of g of C per hectare, a value of 8190 kg C $ha^{-1}$ $y^{-1}$ was obtained for the study area. This would be the maximum amount of C usable by the consumers being exploited.

**Discussion**

The result obtained for NPP was very similar to that described by Thébault et al (2008) for reconnected salt ponds in San Francisco Bay, where nutrient load was also high. From the results of these authors, a trophic transmission efficiency from NPP of 3% for planktivorous fish and 14% for invertebrates can be inferred. These coefficients would correspond to respective maximum potential production values of 245 and 1146 kg C $ha^{-1}$ $y^{-1}$. Assuming a 40% C content in fishmeal (FM), the above figures would approach to 612 and 2865 kg FM $ha^{-1}$ $y^{-1}$, respectively. However, in this type of aquatic system, losses of natural production are significant, particularly those due to predation by wildlife. Therefore, to optimize the production of aquaculture food resources, it is necessary to develop specific management practices, implementing different ecosystem services in the economic balance of the activity. Land availability is assumed to be high since a recent inventory of 90,800 $km^2$ of preserved tidal marshland worldwide (Murray et al., 2022) suggests that over 280,000 $km^2$ of marshland has been altered in some way. It can be concluded that rehabilitating marshes fringing eutrophic estuaries and using simple, unfed aquaculture practices based on water management is a practical option to provide important and recognized ecosystem services such as access to new net aquaculture food resources of high nutritional quality, removal of excess estuarine nutrients to prevent coastal eutrophication and trophic support for wildlife preservation.

**Introduction**

Marine aquaculture production relies primarily on wild-caught fish as feed ingredients such as fishmeal (FM) and fish oil (FO). These key ingredients are generally recognised as highly valuable as they meet nutritional needs for fish growth, being easily digestible and containing high levels of long-chain polyunsaturated fatty acids (PUFA).

The levels of contaminants and nutrients in fish from aquaculture and wild-caught sources are a timely and relevant issue for food safety. Contaminants such as heavy metals and metaloids (metal(oids)), PCBs, DDT, and PAHs pose toxic risks due to bioaccumulation, while nutrient levels like Se, Zn, and Fe vary depending on diet and habitat. After a comparison between aquaculture and wild fish in terms of metal(oids), other contaminants, and nutrients, due to the difference in their environmental conditions, feed and origin, it can be said that higher concentrations of some metal(oids) were observed in wild fish than in aquaculture as well as in other contaminants. The mean Hg and As concentration in wild fish was 0.06 and 3.26 μg/g, respectively, while in aquaculture fish was 0.038 and 1.23 μg/g. The DDT mean concentration in wild fish was 196.48 ng/g, while in aquaculture fish was 44.64 ng/g. The difference in these concentrations does not only depend on the production system, other factors such as age, physiological state or the degree of environmental pollution can have a considerable effect. Therefore, there is a stronger trend toward replacing FM rather than FO because protein alternatives like insect meal and poultry by-products are more nutritional, accessible, like FM and cost-effective. Another critical motivation for seeking alternative ingredients is the reduction of metal(oids) in farmed fish. By incorporating alternative protein sources with lower contamination levels, it is possible to enhance the safety and quality of aquaculture products while maintaining sustainable production practices.

Taking all mentioned above into account, the purpose of this research was to explore the effect of feeding with different alternative proteins (compared to fishmeal) on the composition metal(iods) in Sparus aurata fillets at two growing stages (300 and 800 g).

**Materials and methods**

Three types of feed formulations (n=3, CTRL: fish meal-based diet, PAP: processed animal protein-based diet, and ALT: alternative protein-based diet). Fish sampling took place at two growth stages: when fish reached 300 g and 800 g. The nomenclature for fish was as follows: i) individuals reached 300 g: CTRL300, PAP300 and ALT300; and, ii) individuals reached 800 g: CTRL800, PAP800 and ALT800. Inductively coupled plasma mass spectrometry (ICP-MS) was used for quantification of metal(oids). 0.5 g of freeze-dried sample was weighed into the Teflon cups of the microwave digester, 7 mL of $HNO_3$ 69% ppt quality were added, the tubes were left open for 1 hour pre-digestion and 2 mL of $H_2O_2$ 30% ppt quality were added. HPLC-ICP-MS (Shimadzu, Japón) was used to analyse speciation of As: AsIII (inorganic arsenite), AsV (inorganic arsenate), AsB (arsenobetaine), AsC (arsenocholine), DMA (dimethylarsinic acid) and MMA (monomethylarsonic acid).

*(Continued on next page)*

**Results and discussion**

Regarding metal(oids), the median and mean values were similar in most cases. Overall, our results align with findings in the literature that highlight the influence of fish size and feed formulation could affect the accumulation of them. As concentrations were higher in 800 g fish than in 300 g fish (1.5 times more in CTRL800, 1.3 times more in PAP800, and 1.6 times more in ALT800), with significant differences observed between formulations. Specifically, CTRL showed the highest concentrations, with FM800 having 3.7 times more As than the other diets, and CTRL300 having 3.3 and 4.0 times more than PAP300 and ALT300, respectively. Among As species, AsB was the unique species detected in samples. Recently, the European Commission asked EFSA for a risk assessment on complex organoarsenic species in food. They are typically found in marine foods and comprise mainly arsenobetaine (AsB), arsenosugars and arsenolipids. Following with the rest of the contaminants and potentially toxic elements, Hg levels were also higher in 800 g fish compared to 300 g fish (3.6 times more in CTRL800, 5.1 times more in PAP800, and 6.8 times more in ALT800). While no significant differences were found between formulations, a trend was observed with FM showing higher levels than PAP and ALT. Cd content was generally higher in 800 g fish (2.8 times more in CTRL800, 3.7 times more in PAP800, and 4.4 times more in ALT800), although the median was lower than the mean in 800 g fish across all formulations. Pb concentrations were higher in 800 g fish compared to 300 g fish, though no significant differences were observed. It is noteworthy that the median and mean values were not similar for PAP800 and ALT800. Overall, 800 g fish had considerably higher Pb concentrations than 300 g fish, with increases of 18.9 times in FM800, 18.6 times in PAP800, and 17.1 times in ALT800).

**Conclusions**

The differences between formulations, particularly in As and Hg levels, emphasize the need for a careful selection of feed ingredients to minimize metal(oids) exposure in aquaculture. Further research is needed to better understand the mechanisms governing these compounds metabolism and to evaluate the potential health risks associated with their accumulation in farmed fish.

# OBSERVATION OF ANEMIA IN POOR-PERFORMING RAINBOW TROUT (*Oncorhynchus mykiss*) WITH NEPHROCALCINOSIS IN HATCHERIES

Yanran Cao*[1], Anne Elin Varhaugvik[1], Malin Hoem Storholt[2], Bjørk Ane Nilsen Leira[1], Nora Vadset Roald[1], Silje Kristin Lid[1], Christine Jægtvik[1], og Grete Hansen Aas[1]

[1]Institutt for biologiske fag Ålesund, NTNU
[2] Hofseth Aqua
Email: yanran.cao@ntnu.no

**Introduction:**
Nephrocalcinosis has become a growing problem in Norwegian hatcheries for salmonids. The disease is considered an important cause of reduced welfare, reduced growth and increased mortality. Poor-performing fish, often referred to as "losers," also represent a significant problem in the hatchery phase in salmon (Salmo salar) and rainbow trout (Oncorhynchus mykiss) farming. The underlying causes are multifactorial and remain poorly understood.

The primary aim of this study is to investigate histological and hematological changes in rainbow trout (Oncorhynchus mykiss) during the hatchery phase, with the goal of identifying factors associated with nephrocalcinosis and the development of the loser phenotype.

**Material, methods and results:**
Kidney and blood samples were collected from 15 loser fish (98 ±31 g) and 15 apparently healthy fish (201 ± 36 g) from local hatcheries (Fig. 1). Bleeding was not detected in any of the fish. Histological evaluation revealed well-developed nephrocalcinosis in all loser fish, corresponding to grade 2 or 3 lesions. Among the healthy fish, 6 of 15 displayed mild mineral precipitation and dilation of Bowman's capsule. Additionally, two individuals exhibited grade 2 or 3 nephrocalcinosis, despite being classified as healthy (Fig. 2). Hematological analysis revealed a significantly lower hematocrit (HCT) in loser fish (19 ± 4%) compared to healthy individuals (29 ± 3%; $p < 0.05$; Fig. 3). Plasma cortisol levels were also markedly elevated in loser fish (17.9 ± 7.3 ng/mL) relative to healthy controls (4.4 ± 2.5 ng/mL, $p < 0.001$). However, plasma glucose concentrations did not differ significantly between the groups.

**Conclusion:**
These results indicate a strong association between advanced nephrocalcinosis, reduced hematocrit, and the loser phenotype. Impaired excretory function and anemia may contribute to the syndrome's development. To further explore causative mechanisms, subsequent analyses will include comprehensive blood chemistry profiling, stress biomarker evaluation, and measurements of erythropoietin levels. In the next phase, we will longitudinally monitor the progression of nephrocalcinosis, loser syndrome, and hematopoietic disturbances from early juvenile stages (20 g) up to 200 g. These observations will be correlated with detailed renal histopathology, and the potential influence of seawater transfer and vaccination will also be assessed.

# VALIDATION OF DIRECT MEASUREMENT OF FECAL CORTISOL METABOLITES IN ATLANTIC SALMON (*Salmo salar*) USING A COMMERCIAL ELISA KIT

Yanran Cao, Jingwen Ding, Ernestine Fanjara, Grete Hansen Aas and Anne Stene

Department of Biology Science
Norwegian University of Science and Technology
*Ålesund*, Norway
Email: yanran.cao@ntnu.no

**Introduction:**
Atlantic salmon farming represents a cornerstone of Norway's aquaculture sector, with a production output of 1.6 million tons in 2021. Ensuring high standards of fish welfare is essential to support the industry's sustainable development. Compared to traditional plasma cortisol measurements, the assessment of fecal cortisol and its metabolites (FCMs) offers a less invasive and more efficient approach for evaluating the health and welfare of salmonids. This method not only reduces handling related stress but also supports long-term sustainability in aquaculture practices.

The primary aim of this study is to evaluate the performance of four commercial ELISA kits for quantifying FCMs in Atlantic salmon (*Salmo salar*), and to further investigate the distribution of FCMs across the liquid, solid, and homogenized total fractions of fecal samples.

**Material and methods:**
Atlantic salmon used in this study were reared at a commercial fish farm located on the northwestern coast of Norway. Fecal samples were collected both prior to and 24 hours after sea lice counting procedures conducted in a commercial sea cage. Samples were obtained via stripping and partially subjected to centrifugation to separate liquid and solid fractions. FCMs were analyzed using two methods: enzyme-linked immunosorbent assay (ELISA) and liquid chromatography–tandem mass spectrometry (LC–MS/MS).

**Results:**
Biological validation demonstrated that both the Cayman and Neogen kits detected biologically meaningful changes in FCMs following stress induced by sea lice counting procedures and handling. Analytical validation demonstrated high accuracy, reliability and reproducibility of both kits. The specificity test revealed that the Neogen kit exhibited relatively higher cross-reactivity to cortisol and its metabolites compared to the other kits. Cortisol and four of its metabolites (5β-THF, cortisone, 5β-DHE, 5β-THE) have previously been identified as reliable stress biomarkers in farmed Atlantic salmon. In this study, all five compounds were successfully detected in the total, liquid, and solid fecal fractions using LC–MS/MS. Analysis revealed no significant differences in the concentrations of FCMs across the three fecal components (Fig.1). Strong correlations were found among the sample types ($p<0.05$), indicating consistent distribution of these biomarkers. Similar patterns were observed when concentrations were measured using ELISA, with values across the fecal fractions remaining consistent (Fig.2). FCM concentrations determined via ELISA showed a strong positive correlation with LC–MS/MS measurements ($p<0.05$), although the LC–MS/MS technique consistently produced higher values ($p<0.05$). Moreover, the FCM concentrations measured directly from the liquid fecal fraction using ELISA without prior extraction correlated well with the results obtained from extracted samples ($p<0.05$; Fig.2).

**Conclusion:**
In conclusion, these findings emphasize the need for thorough validation of ELISA kits prior to their application in stress monitoring. Among the kits tested, the Neogen ELISA kit demonstrated reliable performance for quantifying FCMs in Atlantic salmon. The study also confirmed that FCMs are uniformly distributed between the liquid and solid components of fecal samples. While LC–MS/MS remains the more precise and sensitive method for FCMs analysis, ELISA provides a practical and accessible alternative for routine use in most laboratories. Notably, FCM concentrations measured by direct ELISA analysis reflected those obtained using LC–MS/MS, supporting its utility for non-invasive stress assessment in aquaculture settings.

# MACROALGAE PRODUCTION IN THE UK - FROM WILD HARVEST TO AQUACULTURE

E. Capuzzo*, I. MacMillan, T. Ellis

Cefas, Barrack Road
The Nothe
Weymouth, Dorset, DT4 8UB, UK
Email: elisa.capuzzo@cefas.gov.uk

**Introduction**
In the UK, macroalgae or seaweeds have been harvested from the wild for centuries and traditionally used for food, feed and fertilizers. Recently, seaweed biomass has been used to produce bio-stimulants, nutraceuticals, cosmetics, biofuel, bioplastic and biomaterial. An initial attempt to commercially farm seaweed in the 1980s-90s was not sustained. Over the last decade, a resurgence of interest in seaweed has led to the re-development of commercial seaweed aquaculture in the UK. However, no data or centralised information are available on current UK seaweed production from aquaculture or wild harvest.

**Methods**
A combination of literature review, web searches and interviews with seaweed producers, seaweed organisation and regulatory bodies in the UK has been used to determine the status of the UK seaweed industry, including estimates of current production (from both wild harvest and aquaculture), number/extent of farms, and species cultivated.

**Results and discussion**
The seaweed industry is growing in the UK, as the number of farms, seaweed-related businesses and marketed seaweed-products have increased since a previous study in 2016. Species harvested in the UK include brown seaweed (e.g. *Saccharina latissima*, *Laminaria digitata*, *Alaria esculenta*), red seaweed (*Palmaria palmata*) and green seaweed (*Ulva* spp.). Farms use various techniques (longline, droppers, etc.) to suit location, farm size, end uses and local environmental conditions. Growth of the UK industry is hindered by multiple issues, also common to Europe: obtaining licences and investment for prospective farms; lack of standards for farming and products; technological barriers; the need for social licence to operate; spatial planning. It is important to document current activities, so operational lessons (e.g. unproven niche markets; economies of scale and infrastructure; competition from wild harvest and imports) can be learnt by this emerging aquaculture sector.

# EFFECTS OF PROBIOTICS, PREBIOTICS, AND SYNBIOTICS ON TILAPIA (*Oreochromis niloticus*) GROWTH AND IMMUNE RESPONSE IN CONTROLLED AQUACULTURE SYSTEMS

Diego Cárdenas[1] ,Ruth Yolanda Ruiz[1], Luisa Marcela Villamil[1]

[1]Universidad de La Sabana, Grupo de Investigación GIPA - Procesos Agroindustriales

This study investigates the effects of probiotics, prebiotics, and synbiotics on the growth and immune response of Nile tilapia (*O. niloticus*) across various aquaculture systems, based on a systematic review and meta-analysis of the existing literature. The results reveal significant improvements in growth, especially in closed systems like Biofloc and Recirculating Aquaculture Systems (RAS), where microbial stability and prolonged interactions between bioactives and fish are crucial for growth performance. While prebiotics and synbiotics also showed positive effects, their application was less frequent than probiotics, and their field applicability (at production scale) remains inconclusive. Probiotics, on the other hand, positively influenced key immune components, including TLR expression, lymphocyte differentiation, phagocytic activity, and antibody production. Despite these promising results, the study highlights a lack of understanding regarding immune responses in different aquaculture systems, stressing the need for more standardized and comprehensive immune assessments. To advance this research, it is essential to explore the molecular mechanisms behind these effects, particularly using advanced transcriptomic profiling (RNA-seq), to gain a deeper understanding of how bioactives interact with fish immunity. Additionally, gene expression following pathogen challenge assays with pathogens other than *A. hydrophila* should be included, with a focus on emerging diseases of both scientific and practical interest. Applying these findings in commercial-scale aquaculture systems will help integrate these treatments to improve fish health and productivity under real-world farming conditions.

# SPATIAL MANAGEMENT FOR AQUACULTURE PLANNING: DEFINING NEEDS FOR ASSISTING COUNTRIES

F. Cardia[1]*, G. Marino[1], T. Petochi[1], A. Himes-Cornell[2], L. Bowser[2]

[1] ISPRA - Italian Institute for Environmental Protection and Research, Rome, Italy
Email: francesco.cardia@isprambiente.it
[2] FAO -Food and Agriculture Organization of the United Nation, Rome, Italy

The sustainable development of aquaculture increasingly depends on the capacity of countries to integrate sectoral growth of blue economies within a marine spatial planning (MSP) integrated process. Aquaculture has the potential to contribute to food security, coastal livelihoods, and the achievement of the Sustainable Development Goals/Agenda 2030 (Troell *et al.* 2023). However, its expansion often competes for space with other maritime activities and requires a science-based approach to identify suitable areas to be allocated to this activity, minimizing conflicts with other uses. In many regions, MSP has not yet been applied to aquaculture, or only partially introduced, leaving countries without the tools needed to plan for sustainable sectoral growth.

In this context, ISPRA and FAO co-organized in October 2024 the expert workshop "Spatial management for aquaculture planning: Defining needs for assisting countries", held at FAO headquarters in Rome. The workshop brought together 18 experts from different regions of the world, representing diverse experiences and perspectives, to define priorities and outline a roadmap of actions for supporting countries in advancing aquaculture spatial planning. The initiative was motivated by the recognition that knowledge gaps, limited data availability, fragmented governance, and lack of institutional capacity are among the key challenges delaying the integration of aquaculture into the broader MSP processes.

The roadmap outlined during the workshop identifies strategic objectives and actions across five priority areas: (i) governance and institutional frameworks, focusing on streamlined interactions between authorities; (ii) knowledge support for spatial planning in aquaculture, including data, innovative tools, and smart aquaculture; (iii) criteria and guiding elements for allocation of space, co-use of marine areas, land–sea interactions, and adaptation to climate change; (iv) capacity building, awareness, and stakeholder engagement through training and digital platforms; and (v) marine conservation and restoration, emphasizing how spatial planning in aquaculture can contribute to ecological objectives and conservation targets. These directions reflect the need for both technical and policy support, highlighting the role of international cooperation in sharing experiences and mobilizing resources.

The workshop was also aligned with Action XIV of the Updated Joint Roadmap to accelerate Marine/Maritime Spatial Planning processes worldwide (2022–2027), which calls for co-producing sector-specific recommendations on MSP, including aquaculture.
In order to contribute to the development of MSP in the aquaculture sector within the broader MSPglobal framework, the workshop outcomes aim to contribute to the international agenda of extending spatial planning to at least one third of global maritime areas under national jurisdiction by 2030 (IOC-EC 2022). The tools and outputs developed through the workshop are also coherent with the FAO Blue Transformation roadmap (2022–2030), which emphasizes effective planning, governance, and cooperation as essential to sustainable aquaculture development and to the integration of the sector into cross-sectoral policies (FAO 2022).

This presentation provides insights into the rationale for convening the workshop, the process of building consensus among international experts, and the expected outputs in terms of guidance and actions. It also reflects on how this roadmap can serve as a practical contribution, helping countries in integrating aquaculture into MSP in a sustainable way that is sustainable, with a science-based approach, and consistent with global ocean governance objectives.

## Introduction

Despite the socio-economic and environmental importance of the mussel farming sector in Spain, there are currently no monitoring or early warning systems in place to establish mitigation measures against extreme conditions, often exacerbated by climate change.

In this context, the main objective of the project MoMeNTo is to develop an early warning system based on the use of mussels as biosensors, enabling the direct integration of environmental variations into the physiological state of cultivated mussels. To achieve this, a low-cost valvometry sensor developed by CSIC is being used to monitor and characterize valve gaping behaviour as an indicator of thermal stress events, jointly with other classical indicators of physiological stress.

As a first step, a laboratory experiment was developed to relate valve behaviour with other indicators of stress (clearance rate, tenacity of byssus attachment, activity of biochemical biomarkers, histopathological condition), taking also into account the origin of the mussels (Mediterranean or Atlantic) to evaluate different temperature thresholds or strategies to fight heat stress according to their former life-time ecological background.

## Material and Methods

One tank (25 L) with 33 individuals per temperature treatment (8 levels: 16, 18, 20, 22, 25, 27, 29 and 31ºC), and origin (2 levels: Mediterranean and Atlantic) were maintained for 15 days at the target temperatures after an acclimatation ramp of 2ºC/day. Valve behaviour was recorded continuously (10 Hz) during the experiment using hall sensors and a low-cost system developed by IIM-CSIC (Gilcoto et al., 2023). At the end of the exposure time a series of variables were also measured, including condition index (CI), clearance rate (CR), tenacity of the byssus attachment (TEN), histopathological condition and the activities of 5 biomarkers of physiological stress.

## Results and discussion

Preliminary results show common patterns between origins (Atlantic and Mediterranean) on the effect of temperature. Byssus attachment tenacity (TEN) and condition index (CI) showed a decrease as temperature increased, which becomes sharper for temperatures over 25ºC. Some biomarkers, as the activity of the Electron Transporter System (ETS) showed a bell-shaped relationship with temperature and a sharp decline as temperature surpasses the 25ºC, suggesting some kind of threshold at this temperature. Changes in the ETS activity and energy reserves can be related to the activation of the respiratory chain due to an increase in energy costs associated to stress (Andrade et al., 2018).

With regard to their feeding activity, although Clearance rate (CR) also showed an inverse relationship with temperature for mussels from both origins, the Atlantic mussels kept CR values almost constant until temperature surpassed 25ºC (Figure 1A), while mussels from the Mediterranean showed an inverse linear relationship with temperature (Figure 1B). Nonetheless, since CR values were greater for Mediterranean mussels than for the Atlantic ones (5.50± 0.21 and 3.84 ± 0.15 $Lh^{-1}$ respectively), the ability to feed under stress was less compromised in the Mediterranean mussels even at high temperatures. Similar results were previously observed by Lassoued et al., (2021) suggesting the relevance of original habitat conditions on the ability of mussels to adapt.

*(Continued on next page)*

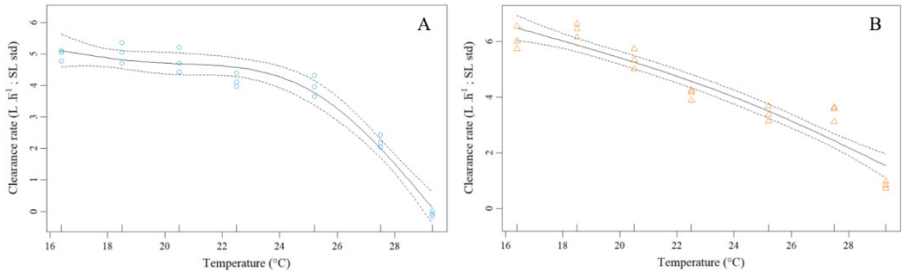

**Figure 1.** CR response to temperature for mussels coming from the (A) Atlantic and the (B) Mediterranean.

Behaviour was also altered by temperature, changing valve opening amplitude, opening time and circadian cycles (Fig. 2). Relationships between valvometry and other physiological indicators of stress are being analyzed to develop machine learning algorithms for the automatic detection of thermal stress episodes based on mussel behaviour.

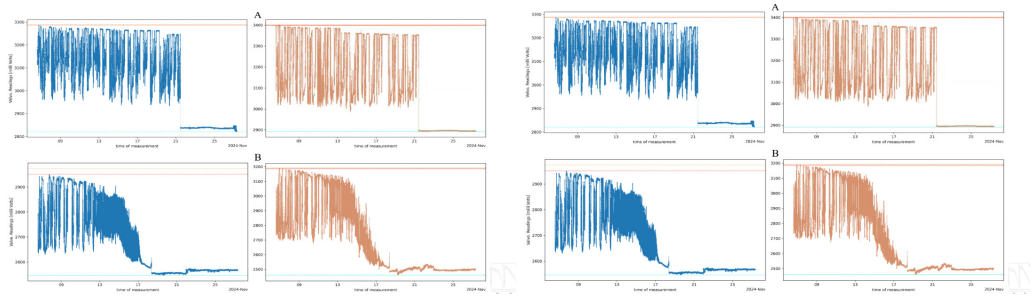

**Figure 2.** Example of the valvometry output from tanks kept at (A)18°C and (B) 31°C.

# A DIETARY PHYTOGENIC NUTRACEUTIC IMPROVES LIPID METABOLISM AND NUTRITIONAL PROFILE IN SEABASS (*Dicentrarchus labrax*) REARED AT HIGH STOCKING DENSITIES

## Introduction

The stocking density is a fundamental aquaculture variable with a huge impact on fish growth performance and welfare. High stocking conditions normally trigger a stress response, and it has been shown that it can decrease flesh quality and fish nutritional value (Zhang et al., 2023). The use of essential oils and phytogenic extracts as dietary additives have been reported to ameliorate fish nutritional quality in terms of fatty acid content (Sáez et al., 2024; Sutili et al., 2018). This study assesses the effectiveness on lipid metabolism and nutritional profile of the phytogenic prototype with sedative properties, FishEase-C (FEC, TecnoVit-FARMFaes Ltd.), in the diet of *Dicentrarchus labrax* juveniles reared at different stocking conditions.

## Materials and methods

Seabass juveniles ($n$ = 438, $w_i$ = 74 ± 18 g, mean ± SD) were placed into 500 L-tanks and distributed in four different experimental groups in triplicate, defined as the combination of feeding (control or FEC diet, 1 mL per kg of feed) and initial stocking density (low density: 4 kg/m$^3$ or high density: 18 kg/m$^3$). Fish were maintained for 70 days under these conditions being weighted and measured periodically. At the end of the rearing period, animals were sampled. Liver was excised to assess changes in intermediary metabolism. Muscle biopsies were taken to assess lipid classes, fatty acid profile, and enzymatic activities from intermediary metabolism. The expression of some target genes of interest were determined in both tissues.

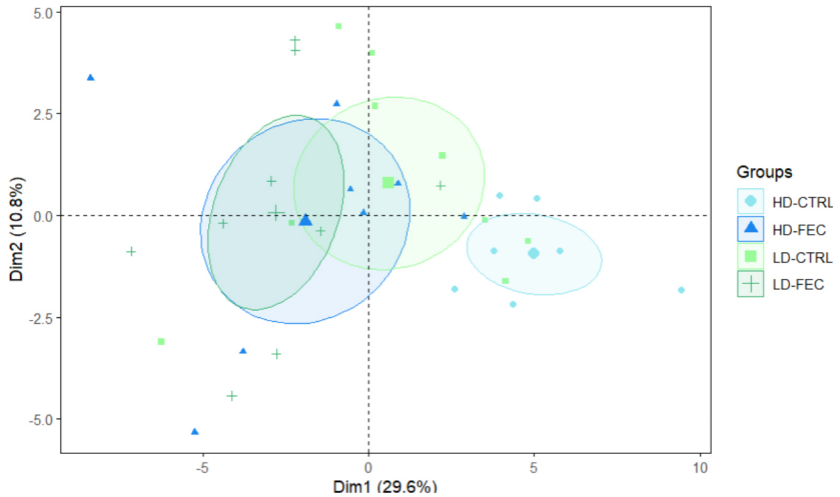

**Figure 1**. Results of the Principal Components Analysis in variables related to the muscle metabolism.

*(Continued on next page)*

**Results**

At end of experimental period, fish almost doubled their weight, but no significant differences on growth parameters were observed between groups. The use of the additive did not induce any negative consequences on fish. The carbohydrate and amino acid metabolism were not affected by the use of FEC prototype, nor by the stocking densities both at liver and muscle of seabass juveniles; however, some changes on lipid metabolism and nutritional composition were determined.

High stocking densities increased hepatic lipid metabolism and mobilization of triglycerides to be used as energy substrate, as it was shown by related enzymatic activities analysed (GPDH, ACL, HADH) and expression of target genes (*apoa1*, *fasn*, *lpl* and *ppar*). The use of the phytogenic prototype does not seem to ameliorate this response in liver.

In the muscle, the main lipid classes were not modified because of density conditions or addition of FEC, being triglycerides the most abundant one; however, the use of FEC reduced muscular total lipid accumulation in animals reared at low density. In addition, GPDH muscle activity decreased by the supplementation of the FEC in fish both at high and low densities, suggesting that triglycerides are not being used as an energy substrate as much as in animals fed with control diet. The fatty acids profile was also modified by stocking densities and use of dietary FEC. This use increased total n-3 polyunsaturated fatty acids (PUFAs) at both densities. It was remarkable the docosahexaenoic acid (DHA) enhancement, at both low and high concentrations, in comparison with specimens fed with control diet. Fish reared at a low density with supplemented diet increased eicosapentaenoic acid (EPA) respect to control animals. Finally, the use of FEC attenuated the decrease in the DHA/EPA ratio induced by high stocking densities.

A multivariate analysis (PCA) was performed to unravel hidden patterns in muscle metabolism (Figure 1), including enzymatic activities and fatty acids profiles. The use of dietary FEC modulates the effect of high stocking density on muscle metabolism, as a differentiation was observed between high stocking density control group and the other three experimental conditions. To conclude, these results support that dietary FEC phytogenic prototype can improve lipid management and nutritional profile in seabass, especially under chronic stress conditions by high stocking density.

**Introduction**

Intensification of aquaculture production often comes linked to increased stocking densities; however, it has been identified as one of the main stressors in the aquaculture industry, increasing the risk of health issues, altering fish behaviour, and causing growth problems. It also has an impact on muscle quality, which is determinant for product quality. *Cannabis sativa* (hemp) has been widely used in humans for its effects as an anxiolytic and anti-inflammatory. The need to find natural products to enhance fish welfare and production efficiency has led to the study of dietary hemp inclusion into fish aquafeed to reduce stress and improve immune status. Several studies in fish suggest that the use of cannabidiol decreases the expression of pro-inflammatory factors, reduces aggressiveness and improves muscular lipid profile (Wang et al., 2023; Bielawiec et al., 2023). This study assesses the effect of a phytogenic additive based on non-psychoactive *C. sativa* (CSNPE) administered through diet on the inflammation process and fatty acid profile in gilthead seabream (*Sparus aurata*) juveniles reared at high stocking densities.

**Materials and methods**

Gilthead seabream juveniles (*S. aurata*) were randomly distributed in 12 tanks (450 L), in a RAS system, establishing four different experimental groups defined as the combination of feeding (control or CSNPE) and the initial density (low stocking density, LSD): 8.5 kg/m$^3$ or high stocking density, HSD): 42 kg/m$^3$). After the 70 days, animals were sampled. Plasma was taken to assess the lipid inflammatory mediator profile; head kidney and liver samples were excised to analyse gene expression markers associated with the inflammatory process, and liver and muscle samples collected to analyse the fatty acid profile.

**Results and discussion**

A PERMANOVA analysis was performed to assess the effect of the inclusion of CSNPE in the aquafeed and the density on plasma lipid mediators. The feed supplementation induced significant changes on plasma EPA derived lipid mediators (Figure 1) (at both stocking densities), and a decrease in 12-HEPE, 15-HEPE and PGE3 were reported in animals fed with the CSNPE diet, with these eicosanoids ascribed as pro-resolving and anti-inflammatory. These results could be due to the fact that in the absence of an acute inflammatory process, there is no requirement for anti-inflammatory lipid mediators in plasma. Additionally, HEPE lipid mediators are substrate dependant, so their reduction might be associated to the *C. sativa* inclusion and its effect on cell recruitment as well as the fatty acids inclusion on lipid membranes. No significant differences were observed for *alox5* and *alox12* gene expression in liver or head kidney, which code for lipoxygenase enzymes required for eicosanoid biosynthesis. At hepatic level, the use of the supplemented diet under LSD conditions increased the *ep4* expression, which is stimulated by prostaglandins and exerts a protective role (Montero et al., 2019).

In liver, decreased levels of EPA, DHA and total polyunsaturated (PUFA) content were found in animals reared at HSD. These changes were attenuated using the CSNPE additive. In muscle, reduction of total n-3, n-6 fatty acids and PUFAs levels were found in animals reared at HSD, however, the additive did not improve the fatty acid profile, and no significant differences were found on the supplemented animals regarding control ones.

Overall, these findings suggest that CSNPE feed supplementation can influence lipid mediator dynamics and partially mitigate the physiological impact of high stocking density in the gilthead seabream.

*(Continued on next page)*

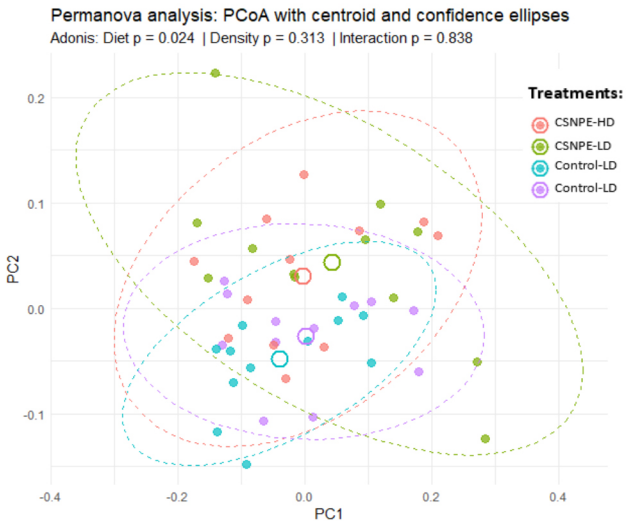

**Figure 1.** Principal Coordinates Analysis (PCoA) for EPA derived lipid mediators and PERMANOVA analysis results. Small dots represent the value obtained for each fish; large dots represent the average of each experimental group; confidence ellipses of each experimental group are also shown. For the multivariate analysis, $p < 0.05$ was considered significant.

## Introduction

In recent decades, the Mediterranean region has emerged as a climate change hotspot, experiencing a marked increase in the frequency, duration, and intensity of marine heatwaves. These extreme temperature events pose a significant threat to coastal ecosystems and the sustainability of marine aquaculture, particularly for temperature-sensitive species (Martínez et al. 2023). Elevated sea surface temperatures can disrupt metabolic homeostasis, suppress immune function, and increase susceptibility to diseases and parasitic infections in farmed fish. Moreover, prolonged heat stress may reduce feed intake, impair growth performance, and compromise product quality (Stavrakidis-Zachou et al. 2021). As the impacts of climate change intensify, there is an urgent need for adaptive strategies to mitigate thermal stress in aquaculture systems. The inclusion of natural bioactive substances in fish diets has shown encouraging results in enhancing thermal stress resilience. Although studies in this area are still limited, nutritional approaches appear promising in mitigating the impact of climate-induced water warming in aquaculture (Pelusio et al. 2020). In this study, the potential of a dietary supplement, consisting of a blend of organic acids and phytogenic molecules (AviPlus®Aqua) and designed to support gut health, enhance nutrient absorption and improve immune function, to improve growth performance, enhance nutrient absorption and resilience against a high temperature stress, was evaluated in a commercially relevant marine aquaculture species.

## Materials and methods

Groups of n.60 10g European seabass (*Dicentrarchus labrax*) were placed into 6 300 l tanks forming part of a marine water recirculating aquaculture system (RAS). Water quality parameters were recorded daily. Fish were first acclimated on the study diets for one week at 25°C with oxygen content >6 mg/l. After the acclimation period, the thermal stress was started and the water temperature was increased by 1°C/day until the final temperature of 30°C was reached and then maintained for an additional 23 days. The start of the acclimation period was considered as day 0, day 7 is considered the start and day 35 is considered the end of the challenge. Fish were weighed on d0 and d35, and additional sampling was performed on d7 and d35 to evaluate performance, condition indexes and gene expression in target tissues with the focus of investigating intestinal integrity (zonula occludens - *zo-1*, occluding - *occl*, aquaporin - *aqp-1*) and stress response and adaptation (heat shock protein - *hsp-70* and *hsp-90*, glucocorticoid receptor - *gr*). Intestinal samples from each treatment (n = 3 per tanks) were collected and stored in NucleoProtect®. RNA was isolated, quantified, and reverse-transcribed in single-stranded cDNA. Relative gene expression of selected markers was normalized using two housekeeping genes (β-actin and ef1α). The comparative Ct method (2-ΔΔCt method, (Livak e Schmittgen 2001) was used to quantify gene expression. The Shapiro-Wilk and Kolmogorov-Smirnov test were performed for normality and homogeneity check, respectively. Results of the different parameters were analyzed using t-test. All statistical analysis were performed using the software GraphPad Prism v.10.4.1 (GraphPad Software, Inc., Boston, Massachusetts, United States). Differences were considered significant when $p \leq 0.05$, and trends were identified when $0.05 < p \leq 0.1$.

## Results

Statistical analyses (Figure 1) reported enhanced positive performance responses of treated diet compared to the control. Treated diet gave the highest final average weight (+ 5%) and SGR (+ 0.14%/day) while achieving the lowest FCR (-5 points), significantly better than that obtained with fish fed the control, indicative of enhanced feed efficiency. Gene expression analysis revealed modulation of the selected markers, suggesting a potential mode of action of the tested phytogenic blends through their capacity to influence barrier integrity and stress response pathways. In conclusion, these results were achieved within a short trial period, highlighting the high potential of these phytogenic blend in supporting fish performance and general health status under thermal stress.

## Introduction

Evidence from fish studies suggests that dietary methionine supplementation can support both innate (Machado et al., 2021, Machado et al., 2018) and adaptive (Martin et al., 2023) immune mechanisms. It is therefore hypothesized that dietary methionine supplementation could be a promising strategy to enhance vaccine efficacy when administered prior vaccination procedures. The present study aimed to evaluate the combined effects of dietary methionine supplementation and vaccination on immune status, antioxidant capacity and response to *Yersinia ruckeri* in rainbow trout (*Oncorhynchus mykiss*).

## Material and Methods

Juvenile trout (5.9 ± 0.9 g) were randomly distributed across 32 tanks (n=35) in a semi-open recirculating freshwater system (14 ± 0.5°C) and fed either a control diet (CTRL, 8.0 mg/g DW) or a CTRL-based diet supplemented with methionine (MET, 17.8 mg/g DW). After 4 weeks, half of the fish within each dietary group were either dip-vaccinated (AquaVac® ERM Concentrate, MSD Animal Health) against *Y. ruckeri* or sham-vaccinated to serve as control. At 21 days post-vaccination, samples were collected from two fish per tank (n=16) to assess bacterial load, hematological parameters, differential cell counts, hepatic metabolites, antioxidant defenses and gene expression, head-kidney gene expression and plasma proteomic profiles. The remaining fish were intraperitoneally challenged with *Y. ruckeri* (5 x $10^5$ cfu/ml) or injected with HBSS as a control. The same parameters were evaluated in 9 fish per group at 4, 24 and 48 hours post-infection. Mortality was monitored daily for 13 days. Fish remained on their respective diets throughout the entire trial.

## Results and Discussion

Prior to infection, MET-fed fish showed decreased hepatic *amd1* expression compared to CTRL-fed fish, a difference that persisted following infection. In unvaccinated fish, post-infection analyses revealed that methionine supplementation appeared to compromise antioxidant defenses, evidenced by decreased hepatic SOD activity, GSH levels, and reduced plasma GPx abundance, and to prolong immune activation, indicated by increased expression of *saa* and *cd8b* in the head-kidney and elevated plasma levels of C1q domain-containing protein and chemotaxin. These alterations coincided with the exclusive detection of *Y. ruckeri* in MET-fed fish at 48 hours post-infection and a lower survival rate (75%) compared to CTRL-fed fish (92.5%). In vaccinated fish, no mortality was observed in either dietary group. However, proteomic analyses at 24 hours post-infection revealed distinct responses: MET-vaccinated fish showed increased abundance of hemostasis-related proteins, whereas CTRL-vaccinated fish maintained a proteomic profile more similar to that of pre-infection fish. This difference may have contributed to the observed trend of slightly faster pathogen clearance in the MET vaccinated fish.

**Introduction**

Aquaculture has emerged as a sustainable alternative to wild-capture fisheries, offering a scalable solution to meet the growing global demand for protein-rich food. In 2022, aquaculture production exceeded 178 million tons and is projected to grow by 5,5% by 2030[1,2]. However, bacterial diseases, remain a major threat to this industry, accounting for significant mortality and over $6 billion in economic losses annually[3,4]. Traditional diagnostic methods (e.g., culture, PCR, omics technologies) are time-consuming, require specialized equipment, and are impractical for early intervention in field conditions[5,6].

To address this challenge, this study —developed at the start-up KOA Biotech and validated in collaboration with the Universitat Autònoma de Barcelona (UAB)— introduces a novel biosensor-based approach for continuous, point-of-care pathogen detection designed for direct application in fish farms.

**Materials and Methods**

Nine whole-cell biosensors were developed using non-pathogenic E. coli DH5a strains carrying HCN plasmids encoding specific receptors constructs, designed to respond to specific signals. These biosensors were first characterized *in vitro* upon lab conditions to evaluate biosensors' sensitivity, specificity and dynamic response range.

Subsequently, to bridge the gap between laboratory and real-world application, four fish pathogens—*Aeromonas salmonicida*, *Vibrio anguillarum*, *Vibrio harveyi*, and *Photobacterium damselae* subsp. *piscicida*— were cultured at low concentrations in water collected from real fish tanks (in the absence of live fish) under controlled temperature, salinity, and nutrient-depleted conditions. Biosensor responses obtained from these experiments were used to train a machine learning classification model aimed at pathogen identification based on biosensor output patterns.

Finally, validation of the integrated biosensing platform (biosensors and hardware) was performed in collaboration with a specialized aquaculture research facility (e.g., CTAQUA). Trials involved exposure to major aquaculture pathogens (*V. harveyi*, *V. anguillarum*, *A. salmonicida*, and *P. damselae* subsp. *piscicida*) under controlled infection scenarios to evaluate the performance of the system under near-real conditions.

**Results**

Biosensors exhibited strong, concentration-dependent activation in response to their cognate signals, displaying both high sensitivity and distinct activation profiles for each biosensor type, confirming their specificity toward different target molecules.

Under controlled aquaculture-relevant conditions (fish tank water without live fish), biosensors successfully detected early pathogen presence even at low concentrations *in vitro*. Each pathogen induced a distinct biosensor activation signature, enabling the generation of preliminary classification models using machine learning approaches for pathogen identification based solely on biosensor responses.
Preliminary in vivo results further explored pathogen identification with biosensor signals within the first days of an infection, suggesting a strong potential for early diagnosis timely outbreak prevention in aquaculture environments.

*(Continued on next page)*

**Conclusions**

This study demonstrates the utility of synthetic biology tools for real-time pathogen detection in aquaculture. The engineered biosensors, integrated with an *in vitro* validation framework and preliminary *in vivo* data, highlight their potential as an effective and scalable point-of-care diagnostic system. The initial *in vitro* setup offers a novel experimental platform to investigate the early virulence stages of pathogenic bacteria and to evaluate the influence of environmental cues on infection processes. This approach enables the development of a high-throughput screening system that circumvents the logistical, ethical, and financial constraints associated with *in vivo* fish trials, while still generating robust and scalable data.

Overall, the early pathogen detection technology developed at KOA Biotech represents a promising step toward sustainable aquaculture management, aligning with FAO objectives[7] to reduce antibiotic dependence and enabling timely, preventive interventions that can mitigate disease outbreaks and improve fish health and farm productivity.

**Introduction**

The full-cycle aquaculture of marine invertebrates requires the metamorphosis induction of the swimming larvae into benthic post-larvae for the grow-out phase. Recent advances in limpet aquaculture used coralline algae and conditioned seawater as natural inducers (Castejón et al. 2024). Compounds with settlement inducing properties, such as acetylcholine, are easier to store and manage than natural inducers and can be applied on demand. The present research determined the influence of acetylcholine on the metamorphosis of the limpet *Patella aspera*.

**Material and Methods**

The broodstock was captured between February and March 2024 and kept in an open system (20 ± 1 °C and 36 ± 1 psu). Gametes were obtained by dissection. Then, the oocytes were matured artificially ($NH_4OH$ at pH 9 during 20–30 min.) and fertilized *in vitro* ($10^5$ sperm cells $ml^{-1}$). Lecithotrophic larvae were cultured in glass beakers and plastic jars (16 °C).

Two assays placed pediveliger larvae 3-day old in culture wells (8 mL) and used two control treatments, filtered seawater as negative control and coralline algae as positive control. First assay tested four acetylcholine (ACH) concentrations (2 to $5\times10^{-3}$ M). Second assay tested $4\times10^{-3}$ M ACH alone and a combination of $4\times10^{-3}$ M ACH with coralline algae. Treatments were applied on larvae 7 and 10-day old, respectively. Assays were finished four days later. The third assay was designed to test the impact of ACH on the completion of metamorphosis. For this purpose, metamorphics (settled specimens that just lost their velum) were obtained by exposing 10-day old larvae to coralline algae for 24h. Then, the metamorphics were exposed to filtered seawater (negative control) or $4\times10^{-3}$ M ACH for three additional days.

Two settled stages were identified: metamorphics (velum loss) and post-larvae (teleoconch and head development). The percentage of settlers (metamorphics + post-larvae) determined the success in starting the metamorphosis and the percentage of post-larvae determined the success in finishing the metamorphosis.

**Results and Discussion**

In Assay 1, the percentage of settlers increased in parallel with the concentration of acetylcholine (Fig. 1a), but no post-larvae were observed in acetylcholine treatments (Fig. 1b).

In Assay 2, the coralline algae alone resulted in a similar percentage of settlers as coralline algae combined with acetylcholine (Fig. 1c), but in this combined treatment the percentage of post-larvae was significantly reduced (Fig. 1d). The third assay confirmed the impact of acetylcholine on the completion of metamorphosis, as the percentage of settled specimens (metamorphics) reaching the post-larval stage (head and teleoconch development) was lower (t-test $P < 0.01$) when exposed to acetylcholine (69 ± 13%) than to filtered seawater (90 ± 7%).

Acetylcholinesterase is a neuronal enzyme found in both vertebrates and invertebrates involved in the hydrolysis of the neurotransmitter acetylcholine. Jiao et al. (2019) identified a high diversity of nicotinic acetylcholine receptor genes in molluscs, suggesting a high diversity of functions, including a likely regulation of early development. The present results supported this hypothesis, as acetylcholine promoted the start of metamorphosis in limpets (velum loss), while inhibiting the completion of metamorphosis. Since in the marine gastropod *Concholepas concholepas* the metamorphosis entails a new form of acetylcholinesterase (Inestrosa et al. 1993), it is congruent to postulate that the regulation of metamorphosis in marine gastropods may require the presence and posterior reduction of acetylcholine levels.

## Introduction

As the aquaculture sector continues to grow at a rapid rate, it is necessary to explore effective nutritional supplements to improve the growth and welfare of the fish. Macroalgae and microalgae have been widely evaluated in the recent years as a novel alternative protein resource for aquafeeds (Gu et al., 2021), and in this regard, algae have been recognized as having promising potential relating to their nutritional value, and sustainability in production. Nevertheless, diets based on vegetable sources continue to present significant challenges for carnivorous fish, as these formulations may limit the efficiency of nutrient digestion and assimilation, and, in certain instances, are associated to the onset of intestinal inflammatory responses (Colombo, 2020). Diet plays an important role in causing intestinal dysbiosis, leading to disruptions to the normal microbial balance. The objetive of this study is to assess the impact of a algae-supplemented diet on microbiota composition of juvenile turbot (*Scophthalmus maximus*) for a period of 180 days.

## Materials and methods

Turbot specimens used in the present study were moved to Marine Aquaculture Plant of Santander (MAPS) (IEO-CSIC, Santander, Spain), where the experiment was conducted. A 6-month start feeding trial was conducted by feeding tanks of turbot. Triplicate groups were fed with 4 differents diet: i) control comercial diet (CTC); ii) A new fish meal diet was formulated (Saéz et al., 2022) and regarded as a control diet (CT), according to the nutritional requirements for turbot; iii) the control diet with a blend of freshwater and marine microalgae supplemented (M5), and iv) the control diet with 5% macroalgae supplemented (*Ulva rigida.*).

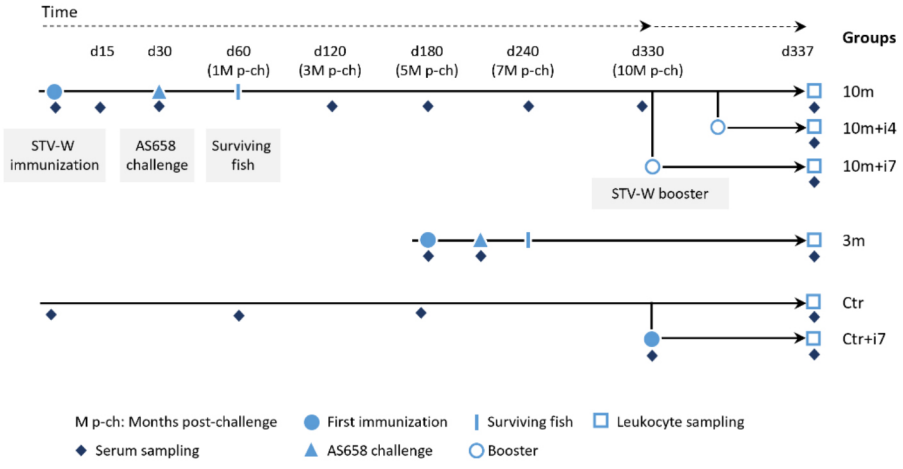

Fig.1. Schematic representation of the immunization schedule for experimental groups to analyze long-term immune responses. Fish were immunized using different protocols (see legend).

*(Continued on next page)*

A total of 72 intestinal mucus samples were subjected to DNA extraction using DNeasy Blood & Tissue kit (Qiagen) and DNA purity and concentration were obtained. DNA metabarcoding library preparation and sequencing were carried out by AllGenetics & Biology SL (www.allgenetics.eu). Sequences were quality filtered and taxonomically assigned following a pipeline using SILVA database. The bioinformatic data processing involved a workflow based on the DADA2 library in Qiime2, and different package of R to analyse taxonomic composition and assess microbial diversity.

**Results and discusión**

The main objective of the study was to assess how the intestinal microbiota of fish responds to feeding with algae-based diets. The preliminary results show that the juvenile turbot accepted the alternate feeding (CT, M5 and U5) diets with no negative effects on survival or growth performance. No differences were observed independently of the diet with respect to diversity alpha (Shannon-index).

In relation to microbiota composition, the phylum with the highest representation was proteobacteria, followed by Firmicutes and Bacteroidota (Fig. 1). M5 and U5 reported an increase of Firmicutes and decrease of Bacteroidota presence compare to the control diets (CT and CTC).

The results suggest that diets M5 and U5 promote a differential shift in the intestinal microbiota of turbot toward the growth of bacteria from the phylum Firmicutes. Based on the results obtained in the microbiota study, the two algae-based diet could be used as additives for aquaculture diet supplementation, although further research is required.

## Introduction

Upon activation, B cells undergo a differentiation process, first becoming plasmablasts and eventually maturing into plasma cells, which possess an enhanced capacity to secrete antigen-specific antibodies (1). These antibodies are a critical component of the specific immune system in fish and play a central role in vaccine induced protection (2). However, a comprehensive understanding of how cell-mediated immunity is orchestrated in fish- including the dynamics of immune response transitions and the mechanisms underlying the generation and persistence of immunological memory-remains incomplete (3, 4). *Solea senegalensis* is a commercially important species in aquaculture, and the development of vaccines is of great interest. Currently, autogenous vaccines offer partial protection against furunculosis, but their efficacy is limited (5). In this study, monoclonal antibodies (mAbs) specific for sole IgM were generated, which allowed us to evaluate the kinetics of $IgM^+$ B cell responses, assess the recruitment of these cells to the peritoneum following vaccination, and compare the dynamics of antigen-specific antibody-secreting cells (ASCs) in the spleen and kidney of primed and boosted fish.

## Material and methods

We evaluated the efficacy of two vaccines formulated with whole (STV-W) or sonicated (STV-P) bacterin from an atypical *Aeromonas salmonicida* strain and the dynamics of the immune responses. All the experiments described in animals were carried out in accordance with the Guidelines of the European Union Council (2010/63/EU). Generation of hybridomas was performed based on the method of Galfre and Milstein (6). The experimental plan for fish vaccination and sampling points for both immunized and control groups are detailed in Fig. 1.

The efficacy of the vaccines was analyzed by challenging sole at 30-, and 90-days post-vaccination by ip. inoculation with a lethal dose that was previously determined in a LD50. The relative percent survival was calculated using the formula: RPS = [1 – (% mortality in vaccinated fish/% mortality in control fish] x 100%. For leukocyte analysis, tissue and peritoneal single cell suspensions (40 µm pore size nylon mesh) were centrifuged onto a 30/51% discontinuous Percoll gradient. Labelled cells were analyzed in a CytoFlex flow cytometer and sorted in a BD FACSAria III. Real-time PCR was performed in a QuantStudioTM 3 System (Applied Biosystems).

## Results

Both vaccines conferred significant protection compared to the non-vaccinated control at 1 month after immunization, which included activation of pro-inflammatory genes, cell mobilization to the injection site, and generation of specific antibodies. The formulation containing whole bacteria (STV-W) showed a better RPS, 48% compared to 34% for the particulated bacteria. However, when the challenge was performed at 3 months post-vaccination, no protection was observed with either vaccine, indicating that these formulations provided short-term protection. To further investigate the response, we have generated two mAbs against sole IgM (CETGA-110 and CETGA-111) for use in various immunoassays, including ELISA, WB, immunofluorescence, and flow cytometry. Immunofluorescence images and flow cytometric analysis of cells labelled with

*(Continued on next page)*

these mAbs revealed a characteristic B cell profile, consistent with B lymphocyte descriptions from other fish species (7). Moreover, the percentages of total sole $IgM^+$ cells in spleen (~30%) and kidney (~7%) isolated leukocytes are comparable to those described for other fish species (8), and FACS-sorted positive populations from these tissues expressed large amounts of both secreted and total IgM. Interestingly, a booster administered ten months post-challenge to previously vaccinated and surviving fish led to activation of ASCs analyzed by ELISPOT, and a more rapid production of specific IgM antibodies compared to primed fish.

**Conclusions**

- Standard autogenous vaccines formulated with the bacterin of *A. salmonicida* subsp. *achromogenes* provide moderate short-term protection in sole, including activation of pro-inflammatory genes, cell mobilization to the injection site, and generation of specific antibodies. However, this protection does not persist beyond three months without a booster.

- A booster administered to vaccinated and surviving fish ten months after the challenge led to an activation of antigen-specific ASCs, and specific antibodies were produced earlier in these fish than in those receiving the vaccine for the first time, indicating that sole is capable of mounting a secondary immune response upon re-exposure.

**Introduction**

Aquaculture is a rapidly expanding sector that is essential to global food security, with fish and seafood consumption projected to increase by 27% by 2030. However, intensive production systems often expose fish to environmental stressors such as temperature fluctuations, hypoxia, salinity changes, and overcrowding that can induce oxidative stress. Reactive oxygen species (ROS) play important roles in the functioning of the immune system, namely in activating various cellular signalling pathways. On the other hand, an excess of ROS can damage cells and trigger cell death. Additionally, potential bacterial infections further exacerbate ROS overproduction.

Grape marc, a residue from the wine industry, is a rich source of antioxidants, due to its high concentration of polyphenols. The antioxidant and antimicrobial potential of grape marc extracts is being explored within the NeoGiANT project that aims to develop and validate innovative natural formulations based on white grape polyphenols for animal production, including aquaculture. In this work, we assessed the potential of three white grape marc extracts, AquaGrapes (obtained with an alcohol, A, a glycol, G, and a ketone, K), to act as modulators of the European seabass oxidative status, by evaluating target oxidative stress markers.

**Material and methods**

Five isoproteic (46%) and isolipidic (19%) diets were formulated to meet the nutritional requirements of European seabass (*Dicentrarchus labrax*) juveniles, including a control and four experimental diets incorporating different formulations of AquaGrapes (alcohol extract at 450 ppm – A450, glycol at 450 ppm – G450 and ketone extract at 450 ppm and 1500 ppm, K450 and K1500 respectively). Diets were prepared using finely ground ingredients, with the AquaGrapes additive added in liquid form during mixing, followed by pelleting (3 mm), drying (60 °C, 48 h), and storage at −20 °C until used. A 48-day feeding trial was conducted in a thermo-regulated recirculating system (15 tanks, 90 L each; 23.8±0.47 °C; 31.7±1.34 ppm salinity; 7.6±0.4 mg/L $O_2$; 12L:12D photoperiod). Juvenile seabass (45 g) were randomly distributed into 15 groups (3 replicates per diet, 15 fish/tank) and fed twice daily until satiety. At the end of the trial, three fish per tank were euthanised and sampled 4 hours post-feeding. The liver was collected and immediately frozen in liquid nitrogen. Oxidative stress enzymes analysis was performed as described in Magalhães *et al.* (2022).

**Results**

Fish fed the G450 diet presented higher levels of catalase (CAT) ($p$=0.016) activity and lower lipid peroxidation (LPO) when compared to the control diet. Superoxide dismutase (SOD), Glutathione peroxidase (GPX) and Glutathione reductase (GR) activities for the diet G450 were higher than the control diet but not statistically different ($p$=0.064, 0.771, 0.778, respectively). Diets A450, K450 and K1500 presented higher absolute values of SOD activity than the control diet, even though these weren't statistically different.

**Conclusion**

AquaGrapes additives, particularly the G extract included at 450 ppm, are promising positive modulators of the oxidative status in aquaculture fish.

# THEORETICAL INTEGRATION OF ESG METRICS AND SDG TARGETS FOR BIOMASS AND BIOACTIVE COMPOUND OPTIMIZATION IN MEDITERRANEAN AQUACULTURE SYSTEMS

Michael Warren G. Ceballos[1,2,3], Shahzad Malak[1,2,4], Saniya Kadankandy Ramesh[1,2,5], Mehtab Ahmed [1,2]

As global aquaculture confronts dual imperatives of food security and ecological sustainability, innovative frameworks are urgently needed to reconcile biomass productivity with environmental and social equity. This study presents a novel theoretical model for Mediterranean aquaculture that embeds Environmental, Social, and Governance (ESG) principles and United Nations Sustainable Development Goals (SDGs) into biomass and target compound optimization strategies. Addressing critical gaps in current sustainability paradigms, we propose a circular bioeconomy approach that leverages Mediterranean biodiversity to maximize resource efficiency while preserving coastal ecosystem integrity.

At its core, the framework introduces dynamic algorithms to balance species-specific biomass yields (finfish, mollusks, algae) with the extraction of high-value compounds (nutraceuticals, antioxidants), guided by SDG 2 (Zero Hunger), SDG 12 (Responsible Production), and SDG 14 (Marine Ecosystems). We conceptualize three interconnected pillars:

1. Multi-Trophic Synergy – Spatial modeling of integrated aquaculture systems to minimize waste and amplify compound recovery.
2. Climate-Adaptive Governance – AI-driven biomass forecasting tools to address Mediterranean warming and habitat vulnerability (SDG 13).
3. Social License Innovation – Metrics linking equitable value-chain participation (SDG 8, 10) to ecosystem service valuation.

Theoretical scenarios demonstrate how precision aquaculture—combining life cycle assessments with ESG-aligned policies—could reduce feed conversion ratios by 15–20% while enhancing bioactive compound yields. By prioritizing endemic species (sea bream, microalgae), the model unlocks niche markets for marine-derived pharmaceuticals, contingent on regenerative practices that protect biodiversity hotspots.

This work challenges traditional productivity metrics, advocating instead for SDG-linked KPIs that quantify carbon sequestration, coastal employment, and nutrient recycling. We further argue that Mediterranean nations, as climate change frontlines, require EU-funded R&D partnerships to operationalize this framework—aligning with AE2025's vision of transdisciplinary innovation.

# TOWARDS ANNOTATION-FREE FISH MONITORING IN AQUATIC ENVIRONMENT BASED ON VISION TRANSFORMERS

## Introduction

Monitoring fish behavior in aquaculture environments is essential for welfare assessment, early detection of anomalies, and production efficiency. However, existing computer vision methods for fish monitoring tasks often rely on large annotated datasets, which are scarce in underwater context due to the time-intensive effort of manual labeling.

This work presents a fully unsupervised pipeline for instance-level fish segmentation and skeletal pose estimation. These pose representations enrich the object-level information beyond the spatial information provided by the bounding boxes in object detection, and also support robust individual tracking and individual behavioral analysis.

Unlike fish segmentation methods based on static background, this approach works under moving camera conditions. Thus, this work contributes to scalable, annotation-free monitoring systems in precision aquaculture.

## Materials and methods

In this work, it is proposed a methodology based on a modular pipeline, illustrated in Figure 1, which comprises three stages designed to transform a video frame into a skeletal pose estimation of individual fish based on keypoints head, body, and tail.

The first stage uses Grounding DINO (Liu et al, 2024), an extension of DINOv2, which learns visual features without labeled data. It integrates language models to associate textual prompts (e.g., ”fish”) with image regions, enabling multi-instance object segmentation without task-specific training.

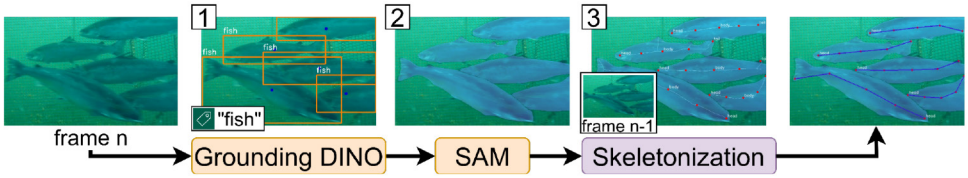

Figure 1: Block-diagram representing method stages pipeline.

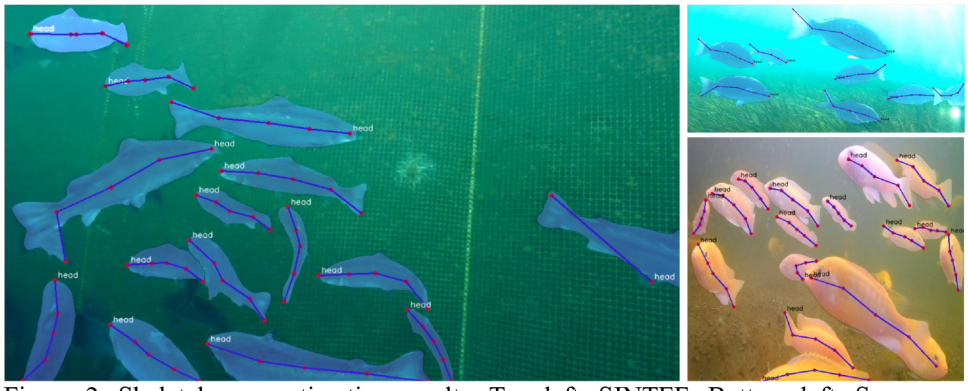

Figure 2: Skeletal pose estimation results. Top left: SINTEF. Bottom left: Seagrass. Right: *Etro plus maculatus*

*(Continued on next page)*

Once fishes are detected, the second stage employs the pre-trained *sam vit h* variant of the Segment Anything Model (SAM) (Kirillov et al., 2023) for instance segmentation, generating accurate binary masks for each fish detected by DINO using the bounding boxes and the centroid points as prompts, without requiring specific domain annotations.

Finally, the third stage involves skeletonizing the binary mask to create a one-pixel-thick representation of the fish, which is then treated as a graph. The longest path in the graph defines the main axis, with keypoints for the head and tail at its endpoints. Optical flow is subsequently applied to refine head-tail assignment based on movement between frames. The body keypoint is located near the centroid of the fish, and two midpoints along the head-body and tail-body segments are computed to more accurately represent its shape. These five keypoints form a reliable basis for tracking and analyzing the shape over time.

This skeletal pose estimation goes beyond traditional object detection and tracking methods, which typically rely on bounding boxes, by enabling the analysis of fish orientation, social interactions, and behavioral responses to environmental stimuli through keypoint based identification.

**Results**

The proposed unsupervised pipeline was evaluated on three publicly available underwater video datasets representing diverse aquatic scenarios. The main evaluation was conducted on the OLAQUA SINTEF dataset, which contains real-world deployment footage from large-scale aquaculture offshore facilities, characterized by camera movements, dynamic backgrounds, high-density fish population, and low image quality conditions.

Additional qualitative assessment was performed on two additional datasets: one with nonconsecutive frames of *Etroplus maculatus*, and Seagrass (Ditria et al.), both recorded in the wild with a fixed camera. Although the latter dataset includes ground truth annotations, only qualitative results are reported for consistency (see Figure 2). Visual inspection of all these datasets confirms the generalization of the pipeline across environments, species, and recording conditions without requiring annotated training data for computer vision deep learning models.

In conclusion, this work presents a novel, fully unsupervised pipeline for fish instance segmentation and skeletal pose estimation in non-fixed underwater camera videos, using recent vision transformer models (DINOv2 + SAM), followed by a skeletonization module. This approach eliminates the need for manual annotations while producing rich spatio-temporal descriptors of fish posture (head-body-tail) that enable fine-grained behavioral insights.

By reducing the annotation burden and enabling pose-aware fish monitoring, this work contributes to scalable, annotation-free monitoring in precision aquaculture.

**Introduction**

The rainbow trout (*Oncorhynchus mykiss*) is one of the most widely farmed freshwater fish species globally, known for its rapid growth, high feed efficiency, and valuable nutritional profile. Its adaptability to various farming conditions makes it an ideal species for evaluating alternative and sustainable feed ingredients. One such ingredient is barley *(Hordeum vulgare* L.), which is widely used as a raw material in the starch industry and generates protein-rich by-products that can be valorised in both the food and feed sectors (Yalcin et al., 2007). In feed production, barley is considered an excellent source of nutrition and energy. Additionally, it plays an important agronomic role by contributing to nitrogen accumulation in the soil, improving soil fertility, and reducing the need for nitrogen-based fertilizers. Moreover, barley's ability to stimulate soil microbial activity makes it a valuable precursor crop in sustainable farming systems (Lammas and Shitikova, 2024).

Beyond its agronomic value, barley also offers substantial environmental benefits, particularly in terms of reducing the carbon footprint of aquafeeds. Preliminary evaluations conducted within the framework of the present study indicate that replacing fishmeal with increasing levels of Barley Protein Concentrate (BPC) can lower greenhouse gas emissions associated with feed production: from 4887.3 kg $CO_2$ eq./ton in the control diet to 4133.5 kg $CO_2$ eq./ton in the diet containing 30% BPC, representing a 15.4% reduction. These findings reinforce the potential of BPC as a climate-friendly alternative ingredient.

In this study, we specifically assessed the effects of increasing dietary inclusions of BPC on growth performance, digestive enzyme activities, intestinal and hepatic histology, and fillet quality traits in rainbow trout.

**Materials and Methods**

Three experimental diets containing increasing levels (10%, 20%, and 30%) of BPC and a corresponding progressive reduction in fish meal content (5%, 2.5% and 0%) were tested. A fourth diet, without the inclusion of BPC, was used as a control. Additionally, astaxanthin was included in all experimental diets to allow flesh pigmentation (salmon coloration) in the trout. Diets were tested on triplicate fish groups of 50 individuals (initial weight: 123 g) over a period of 90 days. During the trial, feed was provided to apparent satiation, temperature was kept at 15.0 ± 1.0 °C and oxygen above 10.5 mg $L^{-1}$. At the end of the trial, final body weight (FBW), specific growth rate (SGR), feed intake (FI) and feed conversion rate (FCR) were calculated. Total alkaline protease, trypsin, chymotrypsin, pepsin, α-amylase, and bile salt-activated lipase were tested to evaluate the enzymatic activity. Histological samples of liver and intestine were taken to evaluate the tissue response. Samples of the fillet were taken to perform instrumental analyses and a sensory panel test to investigate potential organoleptic differences between the diets.

Differences among treatments is considered significant at $p < 0.05$.

**Results and Discussion**

Fish fed diets with up to 20% BPC showed growth performance, feed intake, and feed conversion ratio comparable to the control, consistent with previous findings in salmonids fed with BPC (Bell 2016). At the highest inclusion (30%), slight reductions in growth and nutrient efficiency indices occurred, due to reduced protein digestibility and fiber content.

Digestive enzyme activities were moderately influenced by dietary BPC. Literature on trout suggests proteases and lipases activity can decrease slightly at lower inclusion levels of fishmeal and higher inclusion of BPC, due to anti-nutritional factors (Zaretabar 2021). Nonetheless, enzyme activities remained within physiological ranges, suggesting preserved digestive function.

*(Continued on next page)*

Histological examination of intestinal tissue revealed well-preserved mucosal structure in fish fed up with 20% BPC, with normal villi height and enterocyte integrity. At 30%, minor enteritis or mucosal thinning appeared, as noted in similar studies with high inclusion of plant proteins (Romarheim 2008). Hepatic histology remained within normal parameters, though slight hepatocyte vacuolization or lipid accumulation was observed at the highest BPC level, possibly indicating early metabolic adaptation. Texture and color parameters showed minor variation across diets. Sensory evaluation confirmed acceptable texture and flavor across all groups, though minor differences in some organoleptic properties of flesh were observed, particularly at higher BPC inclusion levels, as noted by de Francesco (2008) in a study with inclusion of a plant protein mixture.

**Conclusion**

Overall, the trial confirmed that moderate levels (10–20%) of BPC can replace fishmeal without adverse effects on growth, health, or fillet quality in rainbow trout, supporting its application in sustainable aquafeeds. Given the global significance of rainbow trout in freshwater aquaculture, it is essential to investigate feed ingredients that can contribute to reducing the carbon footprint of its farming.

# DETERMINATION OF THE WEIGHT OF CUTTLEFISH (*Sepia officinalis*) HATCHLINGS AND JUVENILES WITHOUT MANIPULATION BY COMBINED IMAGE AND REGRESSION ANALYSIS

J. Cerezo Valverde*, F. del Amor Flores, M. Velázquez and C. Espinosa-Ruiz

IMIDA-Centro de Recursos Marinos
30740 San Pedro del Pinatar
Murcia, Spain
E-mail: jesus.cerezo@carm.es

## Introduction

Cephalopods have a soft, elastic and delicate skin, being especially sensitive to handling. In this regard, some authors have reported mortality in cuttlefish (*Sepia officinalis*) during samplings, behaviour changes, small wounds from rubbing against tank walls, and escape and inking responses during cleaning or capture tasks (Forsythe et al., 2002). Skin lesions are also associated with various types of bacterial infections (Farto et al., 2019). In any case, it is sometimes necessary to capture animals to obtain biometric measurements and verify the suitability of a diet or health status. To avoid the risks associated with handling, the objective of this study was to develop a system for monitoring the weight and length of cuttlefish hatchlings and juveniles without removing them from the water.

## Material and methods

Cuttlefish (*S. officinalis*) hatchlings were obtained from wild breeders kept at the IMIDA marine aquaculture station (San Pedro del Pinatar, Murcia). Subsequently, hatchlings were moved at 15 100-L tanks (30 for each tank; stocking density150/$m^2$) and held in a temperature-controlled recirculating seawater system. The animals were fed live adult artemia or mysids for 30 days. Two rectangular pieces of laminated graph paper (14x9 cm) were glued to the bottom of the tanks (Fig. 1A). This study consisted of two phases: 1) obtaining biometric data for the development of equations and 2) applying the method. 1) In 9 tanks, the animals were captured, weighed, and measured at 0, 15, and 30 days of life. Photographs were taken for image analysis using ImageJ (NIH, USA), obtaining the following measurements: body weight (BW, g), total length (TL, mm), dorsal mantle length (ML, mm), body width (WI, mm), and area (A, $cm^2$). Both live healthy animals and those died from unknown causes were included. The data were fitted using regression analysis to a potential curve type lnBW = lna+blnX, where "X" represents the independent variable (TL, ML, WI or A). The best equation was selected based on the highest coefficient of determination ($R^2$) and the lowest estimation error (SEE). The statistical analysis was performed using SPSS Statistics 25.

2) In 6 tanks, overhead photographs were used to obtain biometric data and estimate the BW of cuttlefish according to the equations previously developed without removing the animals from the water. Hatchlings were fed artemia or mysids (3 tanks per diet) for 30 days. From day 30, the juveniles were transferred to 2500 L tanks and fed live shrimp (*Palaemon varians*). Additional measurements were obtained on days 40 and 52 to expand the prediction interval of the model.

## Results

The observed ranges for BW, TL, ML, WI, and A were 0.07–2.48 g, 0.94–3.47 mm, 0.50–2.47 mm, 0.49–1.88 mm, and 0.41–4.79 $cm^2$, respectively. All data fitted the proposed equations to a statistically significant extent ($P<0.001$; Table 1); however, the best variable for body weight estimation was cuttlefish area, which explained 96% of the variance of the data with the lowest error in BW estimation (0.157). Secondly, the ML explained more than 92 % of the variance and showed an error of 0.221. The worst predictors for BW were TL and WI. The images and equations allowed monitoring the biometry of animals throughout trials avoiding manipulation. In this respect, higher estimated body weight was showed in cuttlefish hatchling fed mysids (0.78±0.09 g) compared with artemia (0.51±0.10 g) on day 30 (Fig. 1B).

## Discussion and conclusion

Studies that carry out frequent sampling, even every 5, 7 or 10 days, to determine cuttlefish growth are common (e.g., Sykes et al., 2014). Generally, weight or dorsal mantle length are obtained, since total length or width can be influenced by the animals' elasticity or arm position. In fact, according to our results, higher error was obtained in the estimation of BW as a function of TL or WI. The present study offers an alternative for determining cuttlefish biometry during the early stages of life without manipulating them and contributing to the welfare of this cephalopod during rearing trials.

# SUITABLE DISSOLVED OXYGEN LEVELS FOR SEA BASS (*Dicentrarchus labrax*) MAINTENANCE AT DIFFERENT TEMPERATURES

J. Cerezo Valverde*, F. del Amor Flores and M. Velázquez

IMIDA-Centro de Recursos Marinos
30740 San Pedro del Pinatar
Murcia. Spain
E-mail: jesus.cerezo@carm.es

## Introduction

Sea bass (*Dicentrachus labrax*) is currently the most produced fish in Spain, ranking third in the EU after rainbow trout and sea bream (Apromar, 2024). Its production is carried out in offshore cages, where stocking densities and climatic conditions are highly variable. In this regard, the high temperatures (>28°C) recorded during the summer for more than a decade in the western Mediterranean (https://portus.puertos.es/#/) are remarkable, which can negatively affect fish growth and health. Moreover, these high temperatures increase oxygen requirements, decrease oxygen solubility and promote algal growth in nets, affecting water exchange. In fact, oxygen supply in sea cages has been considered as a limiting factor in stocking density (Besson et al., 2016). The objective of this study was to determine suitable oxygen levels for sea bass at different temperatures according to the response of ventilation frequency and oxygen consumption to progressive hypoxia.

## Material and methods

Sea bass (*D. labrax*) weighing 145±5 g were used, performing two assays at temperatures of 20.4±0.1 and 26.6±0.7°C. In each assay, three replicates of six fish were place in separate 160 L aquaria-respirometers. When the fish were completely acclimated and showed a regular daily feeding rate (2 weeks), they were subjected to a 24-hour fast before measurements. Oxygen consumption ($MO_2$ in $mgO_2$/kg/h) was determined simultaneously in the three replicates from the drop in oxygen concentration at 30-minute intervals after the water supply was stopped. For this purpose, an oxygen sensor (Hatch LDO101), a filter to remove excretion products, a small pump to homogenize the water, and a floating plastic film on the surface to prevent the exchange of oxygen with the air were placed in each aquarium. Ventilatory frequency (Vf) in beats/minute (bts/min) was visually counted in 5 randomly selected fish at 30-minute intervals. The following data were obtained from each replicate: initial Vf at 100 % oxygen saturation (Vfini), maximum Vf reached by a fish (Vfmax), oxygen saturation (% Sat.) where Vf is significantly modified (Ovf), and critical oxygen concentration (Oc) where oxygen consumption decreases significantly ($P<0.05$). Oxygen levels were restored after reaching Oc.

## Results

Initial ventilatory frequency at normoxia (100% oxygen saturation) ranged from 65±3 to 80±6 bts/min, increasing significantly with temperature ($P<0.05$). Subsequently, sea bass responded to the decrease in oxygen concentration by significantly increasing ventilation frequency from 60.7±2.3 % Sat. at 20.4°C and 71.7±6.4 % Sat. at 26.6°C ($P<0.05$). Sea bass behaved as a regulatory organism (Fig. 1), maintaining constant oxygen consumption up to critical values of 44.7±6.4 % Sat. (3.24 $mgO_2$/l) and 65.2±12.9% Sat. (4.24 $mgO_2$/l) at temperatures of 20.4 and 26.6°C, respectively ($P=0.07$). There were no significant differences between Vfmax reached at 20.4ºC (108±1 bts/min) and 26.6ºC (118±9 bts/min; $P>0.05$).

## Discussion and conclusion

In the range of fish weight and temperatures tested, our findings suggest an optimal dissolved oxygen saturation of above 61 % Sat. at 20.4ºC (4.42 $mgO_2$/l) and 72 % Sat. at 26.6ºC (4.68 $mgO_2$/L) where Vf and $MO_2$ remain constant. Below Ovf, circulatory and ventilatory mechanisms would be activated to cover oxygen requirements, but these are energetically costly and negatively affect growth. Values below 45% Sat. at 20.4°C and 65% Sat. at 26.6°C would be dangerous (altered Vf and $MO_2$), activating anaerobic metabolism and lactic acid production. According to Montgomery et al. (2019), Oc values were even lower at 18°C (23.4% Sat; 131 g).

*(Continued on next page)*

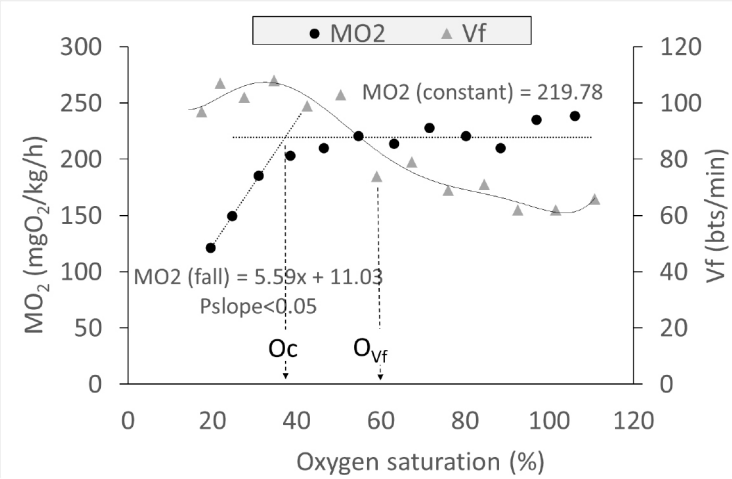

**Fig 1**. Oxygen consumption ($MO_2$) and ventilatory frequency (Vf) as a function of oxygen saturation in sea bass (147 g; 20,4ºC). Critical oxygen saturation (Oc) and the point at which oxygen saturation modifies Vf (Ovf) are marked.

As in other fish species, Ovf and Oc values increase with temperature, indicating that oxygen levels must be higher to cover their metabolic requirements. Ovf values in sea bass were similar compared with *Sparus aurata* (66.8% Sat at 20.5°C and 560 g; Cocco et al., 2009) or *Dentex dentex* (71.4% Sat at 28.1°C and 251 g; Cerezo Valverde et al., 2006). However, the higher Oc values in sea bass at high temperatures (65% Sat at 26.6°C) compared to other species such as *D. dentex* (40.2% Sat at 28.1°C; Cerezo Valverde et al., 2006) were remarkable. These results reinforce the importance of maintaining high oxygen levels (>75-80% Sat.) especially in sea bass during the warmer months due to its greater sensitivity to temperature respect to other species of interest in aquaculture.

E-mail: jesus.cerezo@carm.es

## Introduction

Grey mullets are cosmopolitan fish that can tolerate wide ranges of salinity, temperature and dissolved oxygen levels. This fact has made its aquaculture possible under conditions that are difficult for other aquatic species (Oren, 1981). However, mass mortalities of these fish have also been reported worldwide in estuaries, rivers and coastal lagoons, often associated with low oxygen levels (Zamora-López et al., 2023; Baladia et al., 2025). In this sense, it is relevant for fish farmers a knowledge of the critical oxygen levels where the fish's regulatory mechanisms are unable to meet their metabolic needs, especially at high temperatures. This study describes the respiratory behaviour of the golden grey mullet (*Chelon auratus*) in response to gradual hypoxia at high temperature, paying special attention to the critical oxygen concentration and changes in ventilatory frequency.

## Material and methods

Goden grey mullets (*C. auratus*) from the Mar Menor lagoon (Murcia, Spain) were used. Two triplicate assays were carried out with two different weights and similar temperatures (A1: 3.5±0.1 g and 27.1±0.2ºC; A2: 11.02±0.18 g and 28.1±0.1ºC). Measurements were carried out in 33 and 160 L aquaria-respirometers, where 8 and 18 fish were kept for assays A1 and A2, respectively. When the fish were completely acclimated and showed a regular daily feeding rate (2 weeks), they were subjected to a 24-hour fast before measurements. Oxygen consumption ($MO_2$ in mgO2/kg/h) was determined simultaneously in the three replicates from the drop in oxygen concentration at 30-minute intervals after the water supply was stopped. For this purpose, an oxygen sensor (Hatch LDO101), a filter to remove excretion products, a small pump to homogenize the water, and a floating plastic film on the surface to prevent the exchange of oxygen with the air were placed in each aquarium. Ventilatory frequency (Vf) in beats/minute (bts/min) was video recorded and counted in 5 randomly selected fish at 30-minute intervals. The following data were obtained from each replicate: initial Vf at 100 % oxygen saturation (Vfini), maximum Vf reached by a fish (Vfmax), oxygen saturation (% Sat.) where Vf is significantly modified (Ovf), and critical oxygen concentration (Oc) where oxygen consumption decreases significantly ($P<0.05$). Oxygen levels were restored after reaching Oc.

## Results

Golden grey mullet behaved as a regulatory organism (Fig. 1), maintaining its oxygen consumption constant up to critical values of 30.6±6.0 % Sat. (1.97 $mgO_2$/l) and 37.2±2.2 % Sat. (2.36 $mgO_2$/l) for weights of 3.5 and 11.0 g, respectively ($P>0.05$). Initial Vf at levels close to 100 % Sat. ranged between 94±3 and 195±3 bts/min, with significantly higher values in smaller fish ($P<0.05$). The Vfmax reached was 168±8 bts/min and 234±11 bts/min for fish weighing 11.0 and 3.5 g, respectively ($P<0.05$). The fish responded to the decrease in oxygen concentration by significantly increasing the ventilation frequency from 67.2±7.6% Sat. (4.26 $mgO_2$/l) in 11.0 g fish at 28.1 ºC, although this value could not be obtained in the A1 assay.

## Discussion and conclusion

The results obtained suggest optimal oxygen values above 67 % Sat. at 28.1°C (4.26 $mgO_2$/l) where Vf and $MO_2$ remain constant. (Fig. 1). The extremely erratic behaviour and high variability observed in the Vf of the smallest fish made it difficult to obtain the Ovf in A1. These values are similar to those observed in other marine species from Mar Menor lagoon such as gilthead sea bream or sharpsnout sea bream, where values above 70% ensure the maintenance of metabolism without additional energy cost (Cerezo and García García, 2004).

*(Continued on next page)*

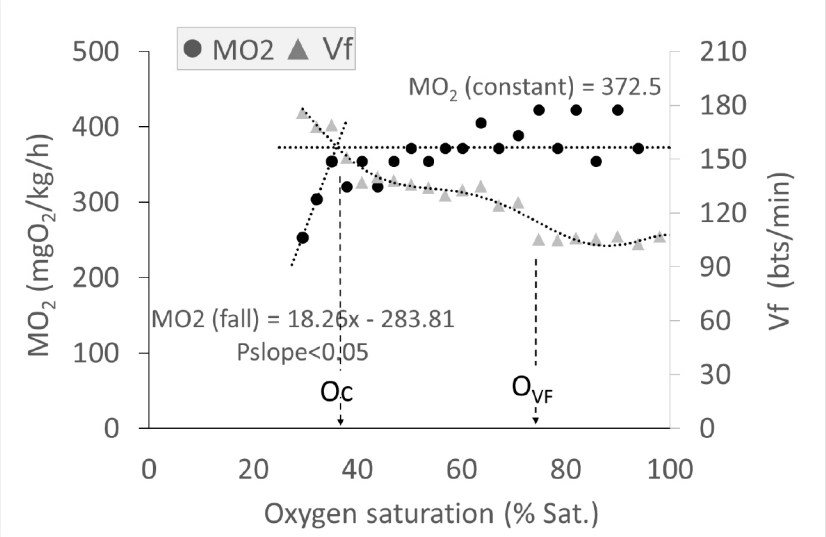

**Fig 1**. Oxygen consumption ($MO_2$) and ventilatory frequency (Vf) as a function of oxygen saturation in golden grey mullet (10.9 g; 28.3ºC). Critical oxygen saturation (Oc) and the point at which oxygen saturation modifies Vf (Ovf) are marked.

Oxygen values below 30.6 % Sat. (A1) or 37.2 % Sat. (A2) would be dangerous (altered Vf and $MO_2$), activating anaerobic metabolism and potentially causing the death of animal in the short term. These values were similar to the sharpsnout seabream (30.2% Sat. at 27.4°C; Cerezo and García García, 2004). Furthermore, in *Chelon auratus*, hypoxia not only generates an increase in Vf but also an increase in swimming activity as a response to find a better habitat. In contrast, these responses involve greater energy expenditure and a higher risk of exhaustion.

Aquaculture plays a critical role in meeting the growing global demand for food. However, the expansion of this industry is consistently challenged by infectious diseases, notably Salmonid Alphavirus (SAV) and Viral Hemorrhagic Septicemia Virus (VHSV), both of which significantly impact rainbow trout (Oncorhynchus mykiss) farming. Mortality associated with SAV infection varies widely, ranging from negligible levels to over 50% in severe outbreaks, whereas VHSV can cause mortalities of up to 90% (1,2).

In this study, we report the design, production, and preliminary evaluation of a novel oral vaccine targeting SAV2 and VHSV, developed using the green microalga *Chlamydomonas reinhardtii* as a biofactory. The antigenic region of the SAV2 E2 glycoprotein and fragment 16 of VHSV were selected and optimized for nuclear expression in *C. reinhardtii* through codon optimization and the strategic insertion of introns. The constructs were assembled using the Modular Cloning (MoClo) system and introduced into the algal nucleus via glass bead-mediated transformation. Western blot analysis enabled the identification of the most productive clone, which was subsequently scaled up and lyophilized to ensure stable antigen expression.

Vaccination was administered via oral intubation in rainbow trout, and post-vaccination responses were assessed by analyzing the expression of correlates of protection-associated genes and IgM titers.

## Introduction

The flathead grey mullet (*Mugil cephalus*) has been recognised as an economically important euryhaline and eurythermal species with potential for aquaculture diversification in the Mediterranean and other regions, such as the Republic of Korea, Taiwan, and South Africa. The species positive attributes for aquaculture include good adaptation to captivity, rapid growth (Whitfield et al., 2012), omnivorous and detritivore feeding habits (Vinatea et al., 2018), and a valued food market including "bottarga" (the roe of fully mature females) with a market value exceeding 200 euros per kilogram. However, a bottleneck for mullet aquaculture development is reproductive control in captivity. Depending on the region and the broodstock holding system, reproductive dysfunctions have been reported to arrest reproductive development. In intensive systems mullet exhibited a severe reproductive dysfunction where the females fail to progress through the vitellogenesis phase and males fail to generate fluid sperm. Studies in IRTA have overcome these severe reproductive dysfunctions with a protocol of weekly injections of recombinant gonadotropins (rGth) (recombinant follicle stimulating hormone – rFsh and luteinizing hormone - rLh) to induce gametogenesis and spawning (Ramos-Júdez et al., 2022). The aim of this study was to use the rGth protocol to induce spawning outside the natural spawning period and further characterise the quality of gametes for larval culture of mullet.

## Material and Methods

The experiment was conducted between March 20th and July 31st, 2023, to induce gametogenesis in mullet using recombinant hormones. The experiment involved 15 mullet randomly selected from a stock of 38 wild adult mullet introduced into IRTA´s facilities (IRTA Aquaculture, Centre de La Rápita, Spain) between 2015 and 2018. Eight females and seven males were divided into an rGths (supplied by www.raraavis-bio.com) group that was treated species specific recombinant follicle stimulating hormone and recombinant luteinizing hormone and a control group treated with saline. The eight females selected for the study had 105.8 ± 5.81 $\mu$m oocyte diameter. The treatments of the females initiated on staggered dates, every two weeks a pair of one rGths female and one control female received the first recombinant hormone and saline respectively. The treatment of each pair commenced on March 20, April 3, April 17, and May 2, 2023. This programmed the spawning of the females to be every two weeks to facilitate live food production for the larval rearing. The rGths (rFsh and rLh) were administered to mullet following the protocol described by Ramos-Júdez et al. (2022). The eggs were incubated under constant conditions, and hatched larvae were transferred to different 100 and 500 L tanks. The larvae were reared with green water (microalgae *Tetraselmis Chuii* and *Isochrysis galbana*), rotifers, *Artemia* and Gemma wean diets (Skretting) based on protocols from Vallainc et al., (2021). Larval growth, development and survival were registered.

## Results & discussion

In the present study, both female and male mullet were induced with rGths to mature and spawn in June – July, a period outside the natural spawning season of wild populations, which typically occurs in September — October in the Western Mediterranean. All four females were during a 13-week period induced from the early stages of pre-vitellogenesis to complete maturation and ovulation. Over a 5-week period, all three rGth treated males developed from having no sperm present to producing and releasing sperm with spermiation sustained for 10 weeks. Three females spawned with males to give fertilised eggs that were incubated and larvae cultured. Juveniles were obtained with a maximum survival of 14.1 ± 5.2% to 42 days post hatch (final experiment day). In contrast, control females and males remained in the early stages of gametogenesis and did not produce viable gametes, highlighting the success of out-of-season induction with rGths. The present study has for the first time demonstrated that rGth hormones can be employed to induce gametogenesis, maturation and spawning of a teleost species

*(Continued on next page)*

out-of-season. Egg and larval quality were sufficient to show that, with further refinement, these protocols can be used by the aquaculture industry as a basis for juvenile production. The high efficacy of induced maturation, over 90% observed in the present and previous studies that developed the protocol, indicate that it offers an attractive alternative for breeder management. Therefore, the findings of this study hold crucial implications for aquaculture, as the culture of this species relies heavily on wild juvenile resources, with hatchery-produced juveniles being scarce.

# THEORETICAL FRAMEWORK FOR A BIOECONOMIC MODEL, DESIGNED FOR A SEA BASS *(Dicentrarchus labrax)* AND FLAT OYSTER *(Ostrea edulis)* IMTA APPROACH IN THE ADRIATIC BASIN

I. Cescon,* F. Nassivera

Università degli Studi di Udine
Dipartimento di Scienze Agro Alimentari
Ambientali e Animali
Via delle Scienze 206
Udine, Italy
E-mail: ivan.cescon@uniud.it

**Introduction**
Aquaculture can be considered a production activity in line with the Sustainable Development Goals (SDGs)/Agenda 2030, due to its important role for food security, nutrition, livelihoods, economies, and cultures. For this reason, it is important to develop pathways for improvement of the sector, that will allow further strengthening of aquaculture's role for contributing to the SDGs (Troell et al. 2023).

Marinet project is born with the scope of promoting and developing a sustainable, secure, and prosperous aquaculture in the Adriatic context.

To reach this scope several objectives were established in this project. One of them is empower small and medium-sized enterprises (SMEs) by sharing research, guidelines, and technological advancements and best practices.

To help fish farmers with decisional support, useful tools are being developed such as bioeconomic models. A bioeconomic-model is a mathematical tool capable of estimate the profitability of an organism production process (Garza, 2024), which in this project is intended to be possibly integrated to an Integrated multi-trophic aquaculture (IMTA). IMTA is the farming, in proximity, of aquaculture species from different trophic levels, and with complementary ecosystem functions (Chopin et al.2012).

The proposed bioeconomic model is developed following Chary et.al (2022) modeling process.

**Definition of the context**
As first step the context is defined. In this project IMTA involves Sea bass (*Dicentrarchus labrax*) and Flat Oysters (*Ostrea Edulis*), farmed in the Adriatic Sea. Offshore cage aquaculture approach is adopted for Sea Bass and Sea Bream farming, which represent the fed species in the IMTA ecosystem. Oysters represent the complementary part of the system, where their role could be defined as "organic extractive species". Among the positive interaction of these organism, we have an important mitigation of eutrophication, possible fed particulate waste reduction and potentially enhanced development of the oysters (Rusco et.al 2025) which can represent a valuable income diversification strategy (Jolly et Clonts, 1993).

**Formulation of the model**
The second step relates to process formulation and model selection, through the consideration of state variables and the equations available to possibly represent the production process. Variables and equation should be carefully chosen, keeping in consideration the context under study, the objectives, the available data and the desired complexity or generality of model among others (Chary et al. 2022).

To be in line with the needs of the farmers, the scope is to proposed an user friendly model, yet capable to provide pragmatic economic key performance indicators (KPI).

A bioeconomic model could be seen as a composition of interacting mathematical sub-models. In an aquaculture context it can be defined by three sub-models, biological, technological and economical (Garza 2024).

*(Continued on next page)*

Biological sub-model aims to predict parameters such as growth and survival, that in the proposed model will be calculated on the basis of Puerto et. al (2023) approach for the sea bass, and Kamiyama et al. (2021) approach for the oysters. These models were selected for their practical relevance to aquaculture and their integration of temperature as a variable, even though the original studies focused on different species, nile tilapia *(Oreochromis Niloticus)* in the former and cupped oyster *(Crassostrea Gigas)* in the latter.

In technological sub-model feed consumption is calculated through feed conversion rate (FCR) literature data (Zoli et al. 2023). Finally economical parameters such in particular costs and revenues are calculated to estimate economic indicators such as: break-even point quantity of production for both oysters and sea bass, profits and other economic performance indexes.

**Implementation and managerial implications**

The model will be implemented in a progressive web application (PWA), that will gather data recorded by farm sensors, farmer in field evaluation and market information. This data will be fed to the model for parameter estimation and they will be also used for model validation. Biological and technological model may be validated through linear regression, confronting predicted data and recorded data (Brigolin et al. 2010). Currently Marinet team, through his AI experts, is also working on the integration of AI in the PWA which will be used to optimize the Bio-economic model.

**Conclusions**

The key feature of the proposed framework is its ability to demonstrate how both the sea bass and flat oyster farming influence the overall economic viability of an IMTA (Integrated Multi-Trophic Aquaculture) farm. Data can be incorporated either from scientific literature or directly from farm records.

It is important to note that this bio-economic model, as a preliminary approach, remains largely theoretical. To enhance its practical applicability, further development is required, including the organization of focus groups with farmers to identify potential modifications and integrations.

# AN OVERVIEW OF THE CURRENT IRISH MARINE AQUACULTURE ENVIRONMENTAL INSITU MONITORING AND FORECASTING SYSTEMS READILY AVAILABLE TO THE INDUSTRIES AND THE NEED FOR FUTURE DEVELOPMENT

T.Chamberlain*, G.Robinson, M.Sammon

An Bord Iascaigh Mhara
Crofton Road
Dun Laoghaire
Co Dublin, Ireland. A96 E5A0
E-mail: Geoffrey.Robinson@bim.ie

Introduction

The Irish Marine Aquaculture industry, spread out in over 282 sites throughout the entire coastline, representing both Shellfish and Finfish ventures, is significantly important to the Irish economy. The potential occurrence of 'Jellyfish blooms', Harmful algal blooms (Habs) and Harmful algal events (Haes) present a continuous challenge to these industries. Annual and seasonal occurrence of growth and transportation of problematic species to aquaculture need to be monitored and potentially predicted in a more integrated manner yet with specific requirements of outputs for each industry. The most recent 2 years proved particularly less biologically and financially problematic in terms of presence of levels of toxic species of algae for the shellfish industries. The Irish salmon industry experienced particularly difficult biological challenges in 2023 and 2024 and '..addressing these challenges remains a priority to stabilise and improve salmon production'(BIM,2023). Through engagement with stakeholders and state bodies, the following overview details the most used insitu environmental monitoring tools and early warning systems and the need for continued improvements.

# ASSESSING WELFARE AND QUALITY IN ATLANTIC HALIBUT (*Hippoglossus hippoglossus*) SLAUGHTERED USING THE *IKI JIME* METHOD

Sherry Stephanie Chan[a]*, Bjørn Roth[a], Atle Foss[b], Børre Erstad[c]

[a]Nofima – Norwegian Institute of Food, Fisheries and Aquaculture Research, Department of Processing Technology, N-4021 Stavanger, Norway
Email: sherry.chan@nofima.no
[b]Akvaplan-niva, Fram centre, 9296 Tromsø, Norway
[c]Sterling White Halibut, 4130 Hjelmeland, Norway

## Introduction

*Iki jime* (also spelled *ike jime*), or brain spiking, is a traditional Japanese method of fish slaughter that involves humane killing through a quick spike to the brain, followed by inserting a thin wire along the spinal column to halt muscle reflexes. This technique aims to extend the pre-rigor period and preserve high fish quality and freshness. However, limited research exists on its welfare and quality implications, and its application on an industrial scale can be challenging. This study evaluated welfare and quality parameters in Atlantic halibut (*Hippoglossus hippoglossus*) slaughtered using the *iki jime* method, compared with the conventional stunning method used in commercial practice.

## Materials and Methods

Due to Norwegian slaughter regulations, the traditional *iki jime* method involving direct brain spiking is not permitted. Therefore, this study adapted the procedure by performing *iki jime* after approved stunning and bleeding methods. While applying the *iki jime* method after stunning, the thick cranial structure of the halibut also caused challenges in wire insertion through the brain. Instead, the tail was removed, and the wire was inserted from the posterior end along the spinal column toward the brain.

In the first study, 20 Atlantic halibut (weight excluding tail: 4.5±0.7 kg) were individually captured using dip nets and percussively stunned. The control group (n=10) were gill-cut and bled in ice slurry. The experimental group (n=10) underwent the *iki jime* method, involving tail removal, wire insertion from the back, and bleeding in ice slurry. Blood samples were collected immediately after the stunning. Postmortem pH and rigor index were monitored for 72 hours. All fish were stored in ice-filled boxes throughout the period.

In the second study, 18 Atlantic halibut (weight excluding tail: 3.5±1.2 kg) were obtained via commercial procedures involving crowding, pumping, stunning and bleeding onboard a vessel. The control group (n=6) was dip-netted from the sea pen and percussively stunned. The remaining fish were pumped onboard the vessel, where one group was subjected to electrical stunning (n=6), and the other to percussive stunning (n=6). All fish were subsequently subjected to the *iki jime* procedure as described above. Blood samples were also collected, and postmortem pH and rigor index were monitored for 72 hours.

## Results

The first study observed no significant differences between the groups in postmortem pH or plasma cortisol levels. Plasma cortisol concentrations were 25.0±19.1 (control) and 35.1±10.1 ng/ml (*iki jime*). Both groups exhibited an initial muscle pH of 7.3±0.1, which declined to 6.1-6.2 after 72 hours. Maximum rigor at 24 hours postmortem.

Similarly, the second study showed no statistically significant differences in postmortem pH, rigor index, or plasma cortisol levels among the groups. Cortisol concentrations averaged below 40 ng/ml across all treatments. Initial pH values were 7.1±0.1 for the control group and 6.8±0.4 and 6.8±0.1 for the percussive and electrically stunned groups, respectively. By 72 hours postmortem, pH values in all groups had declined to between 6.1 and 6.2. Maximum rigor was also reached within 24 hours in all groups.

## Conclusion

The studies demonstrated that the *iki jime* method, while traditionally associated with superior product quality, does not confer significant advantages in welfare or slaughter quality relative to the conventional slaughter methods used in halibut processing. Plasma cortisol levels remained low across all groups, indicating that the slaughter procedures used were gentle and did not induce high stress levels. Therefore, the commercial slaughter methods today deliver both welfare outcomes and product quality comparable to those achieved with the *iki jime* technique.

# SUB-CHILLING AQUACULTURE SPECIES FOR IMPROVED QUALITY AND SHELF LIFE

Sherry Stephanie Chan*, Gorana Drobac, Bjørn Tore Rotabakk

Nofima – Norwegian Institute of Food, Fisheries and Aquaculture Research
Department of Processing Technology
N-4021 Stavanger, Norway
Email: sherry.chan@nofima.no

## Introduction

Sub-chilling is a preservation method that maintains the freshness and prolongs the shelf life of seafood by reducing the temperature to between 0 °C and its initial freezing point, for instance, from -1 to -1.5 °C. This process keeps the fish in a fresh state, rather than frozen. Sub-chilling can be achieved in several ways. Refrigerated seawater (RSW) is frequently used for whole fish, while research on sub-chilled fillets often employs impingement or cryogenic freezing. In the aquaculture industry, sub-chilling fish in RSW onboard vessels immediately after slaughter by the pens allows the delivery of fish already sub-chilled at the early stages of the value chain.

Research also indicated that sub-chilling eliminates the need for ice and reduces meltwater incidence (Rotabakk et al., 2023). Consequently, more fish can be packed and maintained at sub-chilled temperatures until reaching the market, significantly reducing greenhouse gas emissions and costs (Iversen et al., 2021). This presentation provides an overview of studies on sub-chilling for various aquaculture species in Norway.

## Materials and Methods

The studies collectively evaluated the effects of sub-chilling of whole fish in RSW on the quality and shelf life after processing and storage. The species studied included Atlantic salmon (*Salmo salar*), Atlantic halibut (*Hippoglossus hippoglossus*), brown trout *(Salmo trutta*), and Arctic char (*Salvelinus alpinus*).

Whole fish were subjected to sub-chilling in RSW, with the control group being fish stored on ice, the standard method used today. The duration of RSW storage varied by species: salmon for 4 days, and halibut, trout, and char for 1 day. These fish were then stored further with or without ice before processing. Salmon were filleted on day 7, portioned, and packaged in modified atmosphere (MA) (60% $CO_2$:40 % $N_2$), then stored at sub-chilled conditions at -1 °C. For the study on trout, temperature abuse was introduced to mimic possible transport challenges. Quality parameters measured included weight changes, water holding capacity, salt uptake, colour, texture, sensory (odour test, Quality Index Method), and microbiology shelf life.

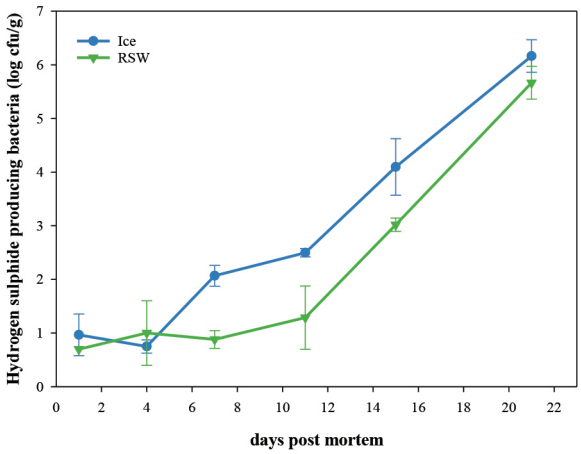

Fig.1: Graph of hydrogen sulphide bacterial growth for Arctic char sub-chilled in RSW for 1 day versus ice-storage.

*(Continued on next page)*

**Results**

Our studies showed that storing gutted salmon sub-chilled in RSW for 4 days resulted in a 0.7-0.9% net weight gain, with improved water holding capacity and higher salt uptake compared to ice storage (Chan et al., 2021; Chan et al., 2020). Additionally, the sensory evaluation (off-odour) and microbiological shelf life were significantly increased, at least doubling during sub-chilled storage packaged in MA (Chan et al., 2024).

For trout, storing in RSW for 1 day also resulted in weight gain, although this effect subsided afterwards. Despite experiencing temperature fluctuations during transport, the quality and shelf life of sub-chilled trout were comparable to those stored on ice. Sub-chilling halibut in RSW for 1 day, followed by packing in boxes with and without ice, extended the microbiological shelf life by 5 days compared to 17 days for the control group. This also corresponds with improvements in sensory analysis (QIM). Moreover, sub-chilling halibut showed a positive effect in mucus removal. Storing Arctic char sub-chilled in RSW for 1 day and keeping them in boxes without ice gave similar microbial growth as the control group. Nevertheless, the growth of hydrogen sulphide-producing bacteria was lower with RSW sub-chilling (Fig. 1).

**Conclusion**

Our studies have demonstrated that sub-chilling in RSW is an effective method for enhancing the quality and extending the shelf life of various fish species. This can be combined with other technologies and contribute to reducing food loss. Therefore, it is possible to package fish under sub-chilled conditions without ice, provided the temperature is properly controlled.

**Introduction**

Rising summer sea temperatures, driven by climate change, pose a significant challenge to the salmon aquaculture industry. Prolonged exposure to temperatures above the optimum range adversely impacts appetite, growth, metabolism, and disease resistance. Although the physiological effects of thermal stress on fishes are well-documented, there is limited knowledge on the molecular mechanisms underlying the thermal stress response in the fish brain. The brain, as the central organ regulating the stress response through the hypothalamus-pituitary-interrenal (HPI) axis and the brain-sympathetic-chromaffin cell (BSC) axis, is highly sensitive to environmental stressors. Moreover, it is a complex organ comprising distinct regions with specific functions, including growth, reproduction, cognition, movement, and metabolism. Investigating various brain regions of salmon exposed to thermal stress conditions would provide insights into region-specific and common stress adaptation mechanisms. Therefore, in this study, we investigated the thermal stress impacts on cerebellum (CBE), hypothalamus (HYP), medulla oblongata (MED), optic tectum (OPT), pituitary gland (PIT), and telencephalon (TEL) of salmon using quantitative proteomics. Additionally, we examined the proteomic profiles of two immune organs, the head kidney (HK) and spleen (SP), to elucidate their roles under thermal stress conditions.

**Materials and methods**

A total of 150 Atlantic salmon post-smolts (mean weight: ~300 g) were randomly allocated to six 500 L seawater flow-through tanks. Three tanks were assigned to the control group (maintained at 15°C) and three to the thermal stress (TS) treatment (temperature increased by 1°C over four weeks and then maintained at 19°C for four weeks). The dissolved oxygen saturation was maintained at 100 % ± 5 % throughout the experiment in both control and TS treatment tanks. At the end of the experiment, six distinct brain regions -CBE, HYP, MED, OPT, PIT, and TEL were collected from six fish per treatment. Additionally, HK and spleen SP were collected from five fish per treatment. Proteomic analysis of samples was conducted using Liquid Chromatography-Mass Spectrometry (LC-MS/MS). Following LC-MS/MS analysis, statistical analysis (p-value $<0.05$, fold change $> \pm 1.5$) were performed to identify differentially expressed proteins (DEPs) between the control (15°C) and TS group (19°C). Finally, bioinformatics tools (DAVID & ClueGO) were used for functional enrichment analysis of the DEPs to identify gene ontology terms and KEGG pathways.

**Results**

An average of over 9000 proteins were identified across the six brain regions. A comparative analysis of DEPs indicated that only two proteins were common across all regions, with the majority of DEPs being unique to specific regions. SERPIN H1 (heat shock protein 47), a well-validated thermal stress biomarker was found to be upregulated in the TEL, HYP, and PIT regions of the TS group. Proteins related to several key pathways and processes, such as amino acid metabolism and protein folding in PIT; endopeptidase activity in TEL, HYP, and PIT; and cardiac muscle contraction, RNA binding, and glucose metabolism in MED, were upregulated. Furthermore, in most regions except MED and OPT, proteins involved in mRNA processing, cytoplasmic translation, spliceosome, RNA binding, and ribosome were downregulated.

*(Continued on next page)*

In HK and SPL, the molecular chaperones SERPIN H1 and HSP90a were upregulated under TS conditions. Bioinformatics analysis revealed that upregulated proteins in HK were enriched in unfolded protein binding and protein processing in the endoplasmic reticulum. In the spleen, notable changes were observed in proteins related to lipid metabolism and protein degradation. Consistent with the brain regions, proteins downregulated in both the spleen and HK were linked to pathways and processes associated with translation and transcription.

**Conclusion**

This study represents the first investigation of the thermal stress response of distinct brain regions (CBE, HYP, MED, OPT, PIT, and TEL) in Atlantic salmon at the proteome level. The differential expression analysis revealed that protein expression varies among regions in response to sub-optimal water temperatures, suggesting that each region may possess a unique adaptation mechanism to cope with thermal stress. Notably, the upregulation of SERPIN H1 across multiple brain regions, as well as in HK and SPL, underscores its critical role in protecting cells from thermal stress-induced damage. Additionally, the downregulation of the transcription and translation machinery in all tissues indicates a possible reduction in the efficiency of the splicing process.

Overall, this proteomic study provides an enhanced understanding of the tissue-specific molecular mechanisms underlying thermal stress adaptation in salmon. These insights have the potential to support the industry in enhancing the resilience of salmon populations to increasing water temperatures induced by climate change. Furthermore, our region-specific brain proteome analysis may serve as a foundational basis for future research investigating the role of distinct brain regions on various physiological processes including behaviour, cognitive function, appetite regulation, energy metabolism, and neuroendocrine responses under varying environmental conditions.

# EVALUATING NUTRIENT CIRCULARITY IN INTEGRATED AQUACULTURE SYSTEMS: CRITERIA AND INDICATORS

K. Chary [1,2,3*] (killian.chary@cirad.fr), C. Jaeger [4], H. M. Jansen [1], S. Harchaoui[4], J. Aubin[4]

[4] INRAE, Institut Agro, SAS, 35000, Rennes, France

Nutrient circularity is an application of circular economy principles that addresses issues such as nutrient accumulation or loss, and a shift away from fossil and synthetic fertilisers. The concept is increasingly being explored and is relevant for managing nutrients more sustainably in agri- and aquaculture systems, but the standards by which nutrient circularity can be evaluated require further clarification, and quantitative indicators should be established. Identifying the nutrient circularity performance of integrated aquaculture systems is particularly relevant to better understand how the combination of multiple and complementary species farmed or naturally present in these systems can upcycle nutrients from waste.

The main objectives of this study were to improve understanding of nutrient circularity and clarify how to quantify it for (integrated) aquaculture systems. To this end, criteria for describing nutrient circularity were first defined based on a literature review, and quantitative indicators were then identified for each criterion to create an indicator framework. Finally, this framework was applied to three contrasting experimental integrated aquaculture systems (i.e. aquaponic, biofloc and polyculture pond) and their conventional monoculture system counterparts from previous studies to test its ability to compare nutrient circularity in aquaculture systems.

Six complementary criteria (and 21 associated indicators) for describing nutrient circularity were identified: productivity, efficiency, self-sufficiency, recycling, regeneration, diversity and complementarity. These criteria, related to circularity principles, provided a clear framework for evaluation. Application of the framework indicated that the integrated systems evaluated usually outperformed conventional monoculture systems, which highlighted the potential of integrated systems to manage nutrients more sustainably. These contrasting integrated systems showed that different pathways (e.g., microbial loops, complementarity between farmed species) can be mobilised to create and (re-)cycle nutrients. Although relatively simple indicators were developed, lack of data prevented quantification of several indicators and thus a full comparison of the systems. Overall, this study helps clarify the concept of nutrient circularity and supports the development of integrated farming systems for more sustainable use of nutrients.

# DEVELOPMENT OF STANDARDIZED *Enterocytozoon hepatopenaei* (EHP) CHALLENGE MODELS FOR VALIDATING DISEASE CONTROL TECHNOLOGIES IN PENAEID SHRIMP (*Penaeus vannamei*)

Thanh Chau, Giang Vo, Khanh Nguyen, Phuc Hoang, Loc Tran

Researcher at ShrimpVet Laboratory
Vietnam
Email: thanhchau@shrimpvet.com

*Enterocytozoon hepatopenaei* (EHP) has become a persistent and economically devastating pathogen in shrimp aquaculture, especially in Asia. The inconsistency between field outcomes and laboratory trials has posed major challenges for the effective evaluation of disease control strategies.

In response, ShrimpVet Laboratory has developed and refined a series of standardized EHP challenge models designed to address this critical gap. This presentation outlines the design, optimization, and validation of three laboratory-scale EHP challenge protocols, grounded in real-world epidemiological observations and disease expression patterns from the Mekong Delta region. These include: **(1)** a cohabitation challenge model using spore-shedding donor shrimp to mimic chronic infections; **(2)** a per os challenge model using homogenized feces collected from EHP-injected shrimp, with a known density of spores, to ensure standardized oral exposure; and **(3)** a combination model, integrating EHP challenge with the induction of White Feces Syndrome (WFS) to better mimic complex, multifactorial field scenarios commonly observed in commercial shrimp production.

Quantification of infection intensity is performed through molecular diagnostics (qPCR), with evaluation of model reproducibility, host response, and sensitivity to treatment efficacy. These models have since been applied to screen a wide range of novel functional feed additives, probiotics, and microbial solutions under standardized yet field-relevant conditions.

By reproducing realistic infection dynamics, ShrimpVet's platform enables precise benchmarking of candidate technologies prior to field deployment. The standardization of EHP challenge models represents a critical advancement for the shrimp health sector, offering a robust and scalable platform for validating next-generation disease management tools. This work supports both innovation and resilience in sustainable shrimp farming systems.

# MOLECULAR PATHWAYS INVOLVES IN MATERNAL IMPRINTING OF EUROPEAN SEA BASS IMMUNITY

Laura Cervera[1,2], Alberto Cuesta[2], Marta Arizcun[1], Elena Chaves-Pozo[1*]

## Introduction

The rapid growth of aquaculture and the intensive culture conditions are leading to chronic stress situations favoring infections including those caused by viruses (Kibenge et al., 2019). Betanodavirus (NNV) is one of the main viral threatens in the Mediterranean coast. In larvae and juvenile stages, NNV infection reaches mortality rates up to 100%, but adults are asymptomatic carriers of infection. NNV can be both horizontal and vertically transmitted (Bandin & Souto, 2020). Focusing on vertical transmission, we must consider the ability of NNV to reach the gonad and establish a latent infection and the transmission of NNV through gametes to their progeny, which is highly susceptible (Valero et al., 2018a). Up to date, vaccines are the preventive method more explored. Although, maternal transfer of immune factors, defined as the transfer of innate or adaptive immune factors by an immunocompetent female to an immunologically naïve neonate has been described in fish (Swain & Nayak, 2009). This process could not explain why female vaccination improve the development of the immune system of the progeny in terms of gen expression up-regulation without promoting the transfer of maternal mRNAs, as recently demonstrated (Valero et al., 2023). Thus, maternal immune priming has been proposed to influence the immune development of the progeny in fish (Valero et la., 2023). However, nothing is known about the molecular pathways that orchestrated this issue. The objective of this study is to identified expression pathways modulated by females' vaccination in both ovary and fertilized eggs using massive transcriptomics.

## Material and methods

The females' specimens of a mature broodstock, but not the males, were vaccinated against NNV with and effective vaccine (pBAD), produced and characterized previously (Gonzalez-Silvera et al., 2019)mortalities in aquaculture industry can reach up to 100%, some species being especially sensitive as is the case of European sea bass (Dicentrarchus labrax and a similar group but sham-vaccinated was established as control. Serum and ovary samples from vaccinated or sham-vaccinated females were obtained 21 days from the vaccination. Several pools of 0.08g of early fertilized eggs, 0 days post-hatching (dph), were obtained from vaccinated and sham-vaccinated broodstocks one year after females' vaccination. Also, larvae from 4 and 9 dph were sampled. Anti-NNV IgM levels were analyzed in females' serum samples (Valero et al., 2018b). Ovary and egg fertilized samples were submitted to mRNA-seq (García-Beltrán et al., 2024). Also, ovary, egg and larvae samples were used to analyze beta-defensins by qPCR (García-Beltrán et al., 2024).

## Results

The efficiency of vaccination was confirmed by the production of anti-NNV IgM antibodies in vaccinated females, but not in the sham-vaccinated group. Transcriptomic analysis revealed the following differentially expressed genes (DEGs): 245 up-regulated and 3179 down-regulated genes in ovary while 3143 up-regulated genes and 4773 down-regulated genes in fertilized eggs, comparing in all cases between control and vaccinated groups. In ovary, there were six KEGG pathways up-regulated: ribosome, oxidative phosphorylation, spliceosome, cell cycle, oocyte meiosis and proteasome. In egg fertilized, there were ten KEGG pathways up-regulated including spliceosome, RNA degradation and mRNA surveillance pathway. Bdef expression was up-regulated at 4 and 9 dph in eggs fertilized from vaccinated females compared to controls.

*(Continued on next page)*

**Discussion and conclusions**

None of the canonical immune pathways resulted altered. This issue together with the transcriptional study of Bdef revealed that their expression increased in larvae from vaccinated-females without a detectable maternal transfer of mRNAs as previously described (Valero et al., 2023). However, we detected some up-regulated pathways that could be related to immunity and viral infection resolution such as oxidative phosphorylation (Li et al., 2019) or spliceosome (Chang & Zhang, 2017). Moreover, other up-regulate pathways such as RNA degradation and mRNA surveillance might be orchestrating the previously observed effect of higher levels of expression of immune-related genes in the progeny from vaccinated-females. In fact, RNA degradation and mRNA surveillance pathway are considered to exert antiviral roles (Balistreri et al., 2017). In conclusion and although further studies are mandatory to ascertain all the molecular mechanism involved, our data suggest that general molecular regulation pathways of the cells might be the clue for understanding the maternal priming of immunity in the fish progeny.

**Introduction**
In recent years, population food demand has been greatly increasing making necessary to diversify marine species to widen the offer to consumers. In this context, greater amberjack (*Seriola dumerili*) constitutes a serious candidate to be introduced in the Atlantic and Mediterranean aquaculture (APROMAR, 2023). However, knowing greater amberjack susceptibility to pathogens is crucial to assess the culture economic viability. One of the most harmful threats to worldwide aquaculture is betanodavirus (NNV). NNV causes high mortality rates in larval stages but causes asymptomatic infections in adult specimens in which NNV triggers a latent infection in their gonads (Bandin & Souto, 2020). Thus, NNV can be transmitted to their highly susceptible progeny (Valero et al., 2018). Therefore, we aimed to find non-lethal NNV-diagnosis methods involving gonadal fluids to detect latent or persistent infections and deeper in the differential immune response triggered in ovary and testis.

**Material and methods**
Adult' specimens of greater amberjack were naturally infected with NNV but remained asymptomatic. Ovarian biopsy, sperm and blood samples were obtained. The expression levels of RNA-dependent RNA-polymerase, *rdrp*, and protein capsid, *cp* were analyzed by qPCR in ovarian and sperm samples following previous protocols (Valero et al., 2015). Also, luciferase activity using RTG *psaumx2-luc* cells was measured in blood samples. Several genes related to antiviral response, antimicrobial peptides (AMPs), inflammation and cell markers were studied by qPCR. Statistical differences between control and infected males or females were studied by Student-t test when normality was assumed and U-Mann Whitney test when data did not meet parametric assumptions.

**Results**
Gene expression analysis of viral markers in gonadal fluids and luciferase activity in blood analysis revealed that 11/14 males were positive for NNV infection while only 5/13 females were so. Nevertheless, qPCR could not detect viral markers in blood while in gonads luciferase activity was undetectable. Regarding the immune response, we observed a great up-regulation of *mx*, marker of the interferon route in males, but no in females. None of the immune related genes were altered in females. In males, T cytotoxic and T helper cells encoding genes were extremely up-regulated. Similarly, AMPs such as histones, hepcidin, lysozyme or complement factor C3 encoding genes were highly up-regulated in testes.

**Discussion and conclusions**
Our data revealed that qPCR is a sensitive method to detect NNV markers in gonadal fluids but not in blood while luciferase method works in blood samples but not in gonadal fluids. These findings lead us to establish new effective non-lethal diagnosis protocols for NNV. Strikingly, great differences in immune response were observed between males' and females' gonads. The lack of immune response triggered in ovary might be a consequence of their physiology as previously suggested (Dias & Brouwer, 2022). Moreover, the generalized tendency to up-regulation of most of the immune markers in the testis point to a persistent infection instead of a latent infection.

## Introduction

The European flat oyster (*Ostrea edulis*) formed a large population of more than 100 million individuals in the Mar Menor (MM) during the 1980s and 1990s. However, its population declined to 6 million individuals in 2006 (Rosique, 2006). Currently, there is an initiative to recover *O. edulis* populations in the MM lagoon as one of the candidate species to mitigate microalgal proliferation caused by anthropogenic eutrophication of the lagoon and promote improvements in water quality and restore its ecological functionality. One of the most important biological processes for maintaining populations is reproductive function and within its puberty, understood as the production of the first wave of gametes is the most critical processes. Although extensive research has been done in adult specimens, gonadal development in the flat oyster during the first reproductive period after attachment to the substrate is poorly understood, with only one histological study available (Cole, 1942). The objective of this study is to understand the gonadal development of the *O. edulis* oyster cultivated and maintained in the MM lagoon, at the histological level, in order to promote oyster cultivation for both future restoration and bioremediation purposes in a lagoon with eutrophic conditions.

## Material and methods

The oysters used in the experiment were obtained from the reproduction of wild specimens collected from the MM lagoon in 2022 (Hernandis et al., 2023) and kept at the Oceanographic Center of Murcia (COMU-IEO), CSIC. Once the spat was obtained at the hatchery and after reaching a size > 20 mm, the sexually immature specimens were transferred to the entrance channel of the San Pedro del Pinatar salt flats, located in the northern basin of the lagoon. This channel, 14 m wide and 330 m long, is supplied daily with water from the lagoon itself, so its conditions are similar to those of the lagoon. The oysters were placed in oyster baskets stacked high off the bottom on cement blocks. Samples were taken to analyze gonadal development (n = 30) using conventional histology (García-García et al., 2016) during two years once a month.

## Results and Discussion

Our results showed that specimens under a year of life had follicles with spermatogenic activity during two seasons of the first year, around May and around November. However, the biggest development of the gonad in terms of gametogenic tissue proportion was observed during May. During the second year of age, we observed the same pattern of gonadal development, but the percentage of gonadal tissue and the time that the gametogenesis stage lasted were higher. However, those parameters during the autumn developmental season kept steady during both years. Moreover, during the gametogenetic autumn stage, no females were observed at any of the two years analyzed. These data are contradictory with previous observations that determined a recruitment spat season during autumn in Mar Menor lagoon (Cano et al., 1997). However, as the population study correspond only with the first two year of live, further studies with mature specimens are needed to clarify this issue.

Regarding gonad morphology, in general, we observed that the majority of individuals presented a gonad composed by follicles where a certain spermatogenic gradation was observed from the inner most part where the most undifferentiated cells were located towards the gonoduct. Among the epithelial cells of the gonoduct, the presence of acidophilic cells stood out. During the first years, only a single specimen in May presented previtellogenic oocytes in the periphery of the follicular acini described as phase 3 of development by Cole (1942). In the second year of life a spring gametogenetic stage occurred with higher percentages of females (second vs first year: 26% vs 10%). Indicating this that females' development need a progressive ontogeny, probably related to hormonal axis development. Issue that has not been properly studied until now and is being analyzed in our laboratory. Although little is known about pubertal development in the oyster, a previous study (Cole, 1942) described a development similar to that found in the oyster from the MM lagoon.

*(Continued on next page)*

**Conclusions**

The gonadal morphology observed during the first two years of life of *Ostrea edulis* pointed to the spring season as the main reproductive one, although a slight development was also observed in autumn. As expected the capability to produce gametes was progressively increased through the first two years of life, as revealed by the increase of the gonadal area through time. Interestingly, the proportion of females detected was also higher in the second year compared to the first one.

**Introduction**

Mountain aquatic ecosystems, due to their oligotrophic characteristics, are particularly sensitive to human activities. Inland trout farming can affect receiving watercourses by increasing nutrients (especially nitrogen and phosphorous compounds), organic matter and suspended solids, as well as through the release of drugs and chemicals. The extent of these impacts depends on several factors, such as farm size, the volume of water diverted, and the self-purification capacity of downstream waterbody. Furthermore, these effects can vary spatially and temporally, influenced by farming practices, stocking densities, feed quality and hydrological conditions. Local impacts are typically observed up to a kilometer downstream of the trout farm, but occasionally, they can extend to a regional scale.

In the Province of Trento, trout farming constitutes a significant production sector with approximately 60 trout farms mainly focused on the rearing of rainbow trout (*Oncorhynchus mykiss*). In this context, the project "Filiera ASTRO: Competitiveness and Sustainability of Mountain Aquaculture" (CUP J38H23001450007), funded by "Piano Nazionale Complementare – PNC" of the Ministry of Agriculture, Food Sovereignty and Forests (MASAF), aims to improve the local aquaculture industry through the reuse of fish farming by-products, and applying new technologies to reduce feed waste and environmental impacts. The project framework consists of four work packages (WP).

The main objectives of WP2 (Environmental sustainability of aquaculture and water courses quality) are: (I) assess specific aquaculture impacts on receiving watercourses, (II) evaluate innovative methods for biological communities (traditional and metabarcoding approaches), (III) identify the best analysis tool to assess the impact of aquaculture on receiving watercourses and (IV) assess efficacy of mitigation measures.

**Methods**

In summer 2024, water quality of the receiving water courses was monitored for a group of 16 trout farms using freshwater macroinvertebrates (Indice Biotico Esteso, IBE) and diatom index (ICMI, Italian Water Framework Directive 2000/60/EC method). Diatom communities were further categorized into ecological guilds to provide insights into trophic conditions. To estimate nutrient enrichment, periphyton samples were collected for chlorophyll-a concentration and ash free dry mass analysis. Water samples were also collected at upstream and downstream stations to retrieve physicochemical parameters (e.g. $O_2$ saturation, COD, $BOD_5$, total phosphorus, nitrate-N, ammonium-N, *Escherichia coli* concentration) and to calculate LIMeco (Italian WFD 2000/60/EC method) and LIM indices.

Farms monitored in this study are characterized by a flow-through scheme, which is widely applied in Trentino, due to rapid water renewal, optimal oxygen concentration and suspended solids removal, which allow optimal rearing conditions for fish. In some facilities, liquid oxygen is applied to support the production, and effluent treatment systems have been implemented to minimize environmental impacts.

Three trout farms that will implement drum filters within the project were selected to assess the mitigation potential. In addition to the previously described methods, quantitative analyses of the macroinvertebrate community were also performed. Five Surber net replicates were collected for one upstream and one downstream sampling station, and macroinvertebrates were identified to genus/family level. STAR-ICMi index, the official Italian method based on freshwater macroinvertebrates under WFD, was also calculated.

*(Continued on next page)*

Main compositional (e.g. 1-GOLD, ASPT, EPT, EPTD, taxa richness, Shannon index) and functional feeding group metrics (e.g. percentage of grazers, shredders, collectors, Shredders/Collectors ratio) were calculated to identify those most sensitive to trout farm impacts. Differences between upstream and downstream stations values were assessed using the Mann-Whitney U test.

**Results and Discussion**

IBE results from the summer 2024 campaign indicate that most upstream stations were in 'Quality Class I', with limited changes observed at downstream stations (where the lowest class recorded is II). These findings agreed with the preliminary ICMI results, showing little or no impact on receiving watercourses. Diatom guild analysis further supported these conclusions, revealing the dominance of oligotrophic and low-profile taxa, which are typical of low-nutrient, and fast-flowing environments.

In all three farms that will apply impact-mitigation measures, %OC (percentage of oligochaetes and chironomids) showed a significant increase observed at downstream stations. In the two most impacted sites (based on IBE), this is accompanied by a decrease in 1-GOLD, ASPT, and percentage of grazers, along with an increase in the percentage of filter feeders. These trends suggest a community shift toward pollution-tolerant taxa feeding on fine particulate organic matter derived from aquaculture effluents, corroborating existing literature.

LIMeco assessments placed most stations in 'Quality Class I', with only three showing lower quality (the lowest being Class IV). LIM appeared to be more stringent, with nearly half of the stations classified as Class II and the rest as Class I. Among chemical parameters, a general increase in total phosphorus and total ammonium concentrations were observed at downstream stations, likely attributable to fish excreta and uneaten feed.

**What's next?**

For the three selected trout farms, biological and chemical analyses will be repeated under different seasonally conditions before-and-after the installation of drum filters. These data, along with a bulk eDNA metabarcoding approach, will be used to assess the effectiveness of the mitigation measures, understand how these methodologies can be integrated and develop new metrics and indices that are specifically suited to detecting trout farming-related impacts in montane lotic ecosystems.

# FROM LAB TO FARM: VALIDATING AN ORGANIC ACID BLEND FOR BACTERIAL DISEASE MANAGEMENT IN FISH

I. Chen*, M. Guerin, G. Hernández, M. Isern-Subich, and W. Nuez-Ortín

Adisseo S.A.S, France
Email: i-tung.chen@adisseo.com

Gram-positive bacterial diseases, particularly those caused by *Lactococcus* and *Streptococcus* species, cause significant economic losses in fish farming. This study evaluated the efficacy of a functional organic acid blend (Bacti-Nil Aqua, Adisseo) against these pathogens in multiple levels through *in vitro*, laboratory, and field trials.

*In vitro* assays determined the minimum inhibitory concentration (MIC) against field isolates of *Lactococcus garvieae*, *Lactococcus petauri*, *Carnobacterium sp*., and *Streptococcus penaecida* from Brazil, Colombia, and the Mediterranean region. The MIC values ranged from 1,000 to 4,000 ppm, confirming consistent antimicrobial activity at commercially feasible concentrations. Subsequently, *in vivo* challenge trials demonstrated the additive's protective effects. In Nile tilapia (*Oreochromis niloticus*) challenged with *Aeromonas* and *Streptococcus*, dietary supplementation reduced final mortality by 22%. Similarly, in rainbow trout (*Oncorhynchus mykiss*) challenged with *L. garvieae*, supplementation lowered mortality by 40% compared to controls ($P<0.05$). These findings were validated in a commercial tilapia farm trial in Thailand, where supplementing the diet with 0.2% of the blend improved the FCR by 3%, increased total biomass by 5%, and yielded a 3.5 return on investment (ROI).

These integrated results confirm that the additive provides consistent antimicrobial benefits across diverse species, environments, and production stages. Its demonstrated efficacy in both laboratory and field settings establishes its value as a practical tool for managing bacterial diseases in aquaculture.

# DIETARY PHYTOBIOTIC ACCELERATES SKIN WOUND HEALING IN A ZEBRAFISH LASER ABLATION MODEL

I. Chen[a]*, C. Hsiao[b], M. Isern-Subich[a], and W. Nuez-Ortín[a]

[a] Adisseo S.A.S, France
[b] Chung Yuan Christian University, Taiwan
Email: i-tung.chen@adisseo.com

## Introduction

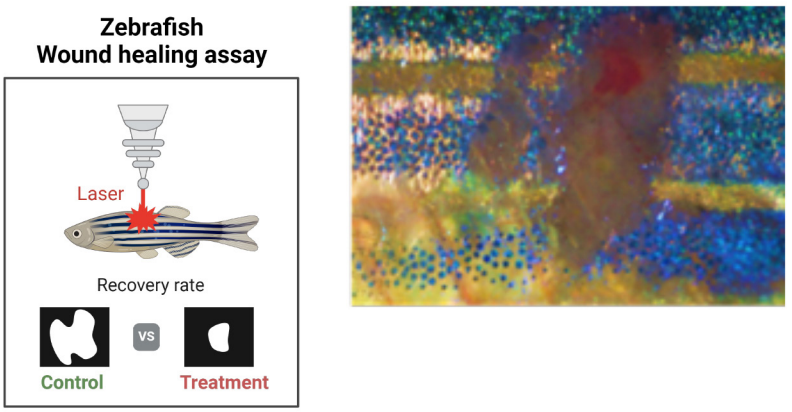
Fish skin functions as the primary barrier against pathogens, mechanical damage, and environmental stressors, playing a crucial role in physiological homeostasis via mucus secretion and osmoregulation. Under intensive aquaculture practices, factors such as high stocking density, frequent handling, and temperature fluctuations often cause skin injuries, compromising the integrity of this protective barrier and increasing susceptibility to infections. Enhancing skin wound healing is thus critical for fish health and aquaculture productivity.

Zebrafish (*Danio rerio*) have become a widely recognized model for studying vertebrate skin regeneration due to their rapid wound closure ability. Recently, a new laser ablation method has provided precise and reproducible control over wound size and depth, further enhancing experimental consistency. The present study utilized the laser ablation model in adult zebrafish to evaluate the efficacy of phytobiotic-based dietary additives in accelerating wound healing and promoting efficient skin regeneration.

## Material and methods

Adult wild-type zebrafish were maintained at 28 °C in 10 L tanks with a 14-hour light/10-hour dark cycle and fed twice daily. Fish were randomly allocated into experimental groups (n=10 per group), receiving either phytobiotic-based dietary additives or PBS control by oral gavage at 500 mg/kg, administered twice weekly for 14 days before injury. Full-thickness skin wounds (~2 mm diameter) were induced using a 3 W laser on the left flank under anesthesia. Following laser ablation, fish were housed individually in aerated 3 L tanks with water renewal every two days, and dietary treatments continued until the trial conclusion. Wound areas were photographed at days 5, 10, 15, 20, 25, 30, and 35 post-ablation and analyzed using ImageJ software, expressed as the wound-closure percentage (WC%). At 10 days post-injury, skin samples were collected, embedded in paraffin, sectioned, and subjected to hematoxylin-eosin (H&E) staining and cytokeratin 18 (CK18) immunostaining to assess re-epithelialization and tissue remodeling activity.

**Figure 1.** Zebrafish skin wound healing assay using laser ablation. A laser was used to create precise skin wounds, and healing was compared between control and treatment groups to assess the effect of dietary phytobiotics.



## Results

Following laser ablation, mortality rates remained low across all treatments and control groups, confirming minimal stress induced by laser ablation. Among the tested additives, APEX (Adisseo), a phytobiotic-based formulation containing a mixture of medium-chain fatty acids and essential oils, significantly accelerated wound healing. Fish treated with the additive achieved 25% wound closure by 9.3 days and 50% closure by 16.2 days, substantially faster than the control group (26.7 days), representing nearly a 40% improvement in skin recovery. Histological assessments and CK18 immunostaining further confirmed enhanced re-epithelialization and tissue remodeling in APEX-treated fish. These findings indicate that dietary phytobiotic effectively stimulate both early and late phases of wound repair. Overall, the finding demonstrates strong potential as a dietary strategy to improve skin resilience and accelerate regeneration processes in fish, potentially reducing dependence on chemical treatments.

# LEVERAGING IMAGE SEGMENTATION MODELS: APPLICATION OF THE SEGMENT ANYTHING MODEL (SAM) IN FISH BEHAVIOUR RESEARCH IN RAS

IH. Chen[1*], N. Belbachir[1], L. Ebbesson[1], N. Gharbi[1], D. Izquierdo Gomez[2], L.E. Solberg[2], J. Kolarevic[2,3], S. K. Kumaran[2,] G.A.N. Helberg[3,4] and C. Noble[2]

[4] Lerøy Seafood Group ASA, Norway
[*] E-mail: chen@norceresearch.no

## Introduction

Automatic monitoring of farmed fish can lead to improvements on feeding management and a better understanding of stress events. We therefore present an algorithmic pipeline to leverage the SAM[1] model to cut out fish segmentations without the need for costly fish annotations. We also realized the downstream tasks of calculating orientation angles and identifying fish that do not swim in similar orientations as their close conspecifics.

## Materials and methods

A top camera with a video resolution of 1080p @ 30fps was installed above each octagon-like tank (6 tanks, volume of 3.3m$^3$ each). A total of 1000 Atlantic salmon with a weight of 40 grams ± 10 grams were placed in each tank. Using segmentation masks from SAM[1] we calculated the orientation of detected fish in video frames. Then we determine if those fish are swimming coherently with its peers by filtering out fish in each k-mean cluster (which used the spatial coordinates of fish) that fell out of the interval with the median absolute distance around the circular median angle of the cluster, respectively. Aggregating the results gave rise to abnormalities scores.

## Results and Discussion

We were able to show that both feeding and panic avoidance could be measured with these three metrics. We also showed that panic avoidance has a stronger spike/fall, meaning the intensity of reaction and the increase/decrease in our metrics was proportional. Further work is needed to differentiate between different behavioral patterns that could occlude results. Additionally, the detection count could be increased in the future to reflect the tank behavior more reliably. Overall, the presented methodology tries to push towards easily accessible and interpretable readings for facility personnel.

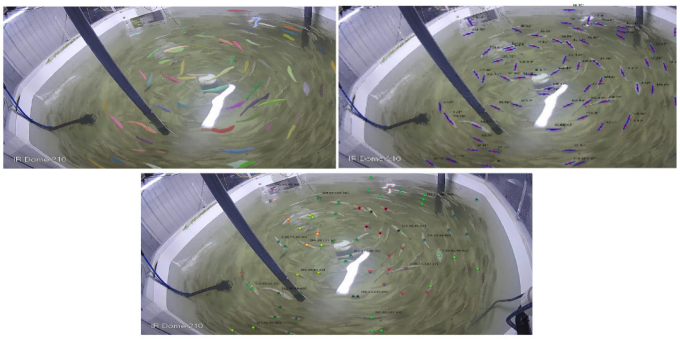

*Figure 1 The algorithmic pipeline from left to right: Segmentation masks (upper left) are used to calculate orientation angles (upper right) which then are used for analysis whether fish are swimming in similar orientations as conspecifics that are nearby (fish in the same cluster have the same dot color). A red triangle indicates that the fish individual is swimming with different orientation than its close peers, a green triangle indicates similar swimming orientation (bottom).*

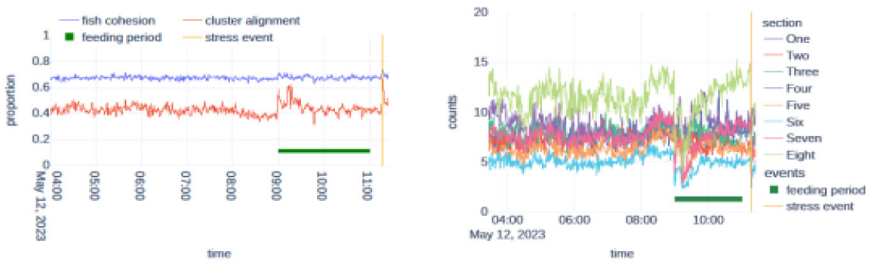

*Figure 2. Fish cohesion and cluster alignment as abnormality scores (left) and the detection counts by tank section (right). The green horizontal line indicates the feeding period, and the vertical orange line the stress event at 11:17.*

Email: ibcty@mail.ncku.edu.tw

Fish inhabit in aquatic environment which is full of pathogens which may cause diseases outbreak. Therefore, fish mucosal immune system, including the mucosal associated lymphoid tissues (MALTs) and immunoglobulins (Igs) serve as the first line of defense in protecting fish from the infection of aquatic pathogens. Grouper which is one of the most economically important species in Taiwan, has been threatened by the nervous necrosis virus (NNV) which can cause almost 100% death for decades. To investigate the grouper mucosal immune system in against to NNV infection, the orange-spotted grouper immunoglobulin T (osgIgT) was cloned and characterized in this study. Real-time quantitative PCR (qPCR) results revealed that osgIgT was highly expressed in grouper MALTs. Moreover, the osgIgT was significantly responsive to the immune stimulants lipopolysaccharide and poly I:C, which mimic the bacterial and RNA viral challenges respectively. Upon NNV infection, the osgIgT transcripts was found upregulated in MALTs, and immunofluorescence analysis demonstrated colocalization of osgIgT with the NNV particles, suggesting a direct role of mucosal immunity against viral infection. Besides, the grouper was treated with different temperatures to investigate the expression of osgIgT upon thermal stresses and the results showed that osgIgT is more responsive to low temperature treatment. In conclusion, this study evaluates the important role of osgIgT in the MALTs of grouper upon viral infection and temperature modulation. These information may contribute to the development of disease management strategies in marine aquaculture.

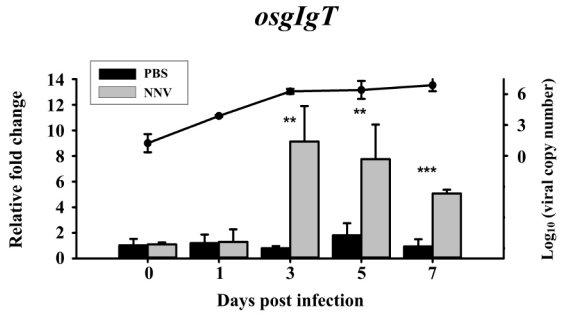

Fig 1. The transcript expression of *osgIgT* in NNV infected orange-spotted grouper larvae at different timepoints were analyzed using qPCR, using *β-actin* as housekeeping gene. The data represented means and standard errors of six fish. Values were compared using the Student's t-test (* $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$).

# ACUTE TOXICITY, BIOACCUMULATION AND ELIMINATION OF PROMETRYN IN TILAPIA *Oreochromis niloticus*

Bo Cheng*, Jianhua Liu, Paul J. Van den Brink

Chinese Academy of Fishery Sciences
Research Center for Aquatic Product Quality, Safety and Standards
No.150, Qingta West Road
Beijing, China
chengb@cafs.ac.cn

Tilapia juvenile were aqueous exposed to different concentrations of the herbicide prometryn to investigate its acute toxicity, bioaccumulation and uptake and elimination rates. First, a 96-h acute toxicity test was carried out. The resulting 96 h $LC_{50}$ was 5.49 mg/L, and the 96 h $LC_{10}$ was 5.02 mg/L. Then, fish were exposed to 0.55 mg/L (1/10 96 h $LC_{50}$) and 0.055 mg/L (1/100 96 h $LC_{50}$) of prometryn solution for 28 days, followed by 14 days of elimination in clean groundwater.

The accumulated concentration levels in various tissues were always higher in the high concentration compared to the low concentration. The highest accumulated concentration of prometryn in various tissues in the 0.055 mg/L treatment were for muscle: 0.136 ± 0.0616 mg/kg (1 d), liver: 3.74 ± 2.95 mg/kg (7 d), gill: 0.971 ± 1.45 mg/kg (1 d) and blood: 0.0716 ± 0.0669 mg/kg (22 d). In the 0.55 mg/L treatment, the highest levels were for muscle: 1.27 ± 0.284 mg/kg (1 d), liver: 16.9 ± 12.7 mg/kg (7 d), gill: 8.11 ± 3.02 mg/kg (1 d) and blood: 0.751 ± 0.0775 mg/kg (22 d). The highest bioconcentration factor (BCF) of 93.1 was observed in the liver when exposed to the low concentration. Besides, for other tissues, the highest BCF were for muscle: 6.03, gill: 32.3 and blood: 2.91, all observed in the 0.55 mg/L treatment. Most of the accumulated prometryn was removed from all tissues within 24 h after the organisms were transferred to clean water. However, management of using prometryn in China aquaculture should be improved to prevent possible ecotoxicological effects and ensure food safety.

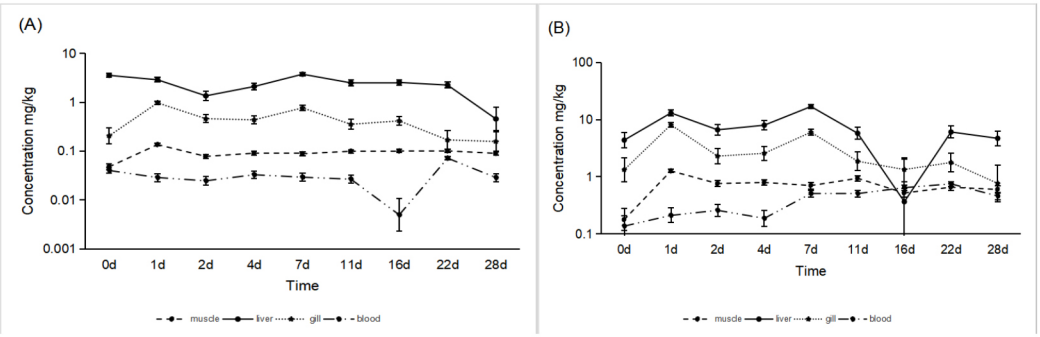

Figure 1. Tissue concentrations of prometryn in the 0.055 mg/L (A) and 0.55 mg/L (B) treatments during the exposure period.

# EFFECTIVE MICROBIAL CONTROL STRATEGIES FOR CONSISTENT HIGH-QUALITY ARTEMIA PRODUCTION

L. Chiappi*, T. De Wolf, K. Seminck, R. Van Raemdonck, L. Marien, B. Hostins, G. Rombaut

INVE Aquaculture Research Center (IARC), 57016 Rosignano Solvay, Italy
INVE Aquaculture, Hoogveld 93, 9200 Dendermonde, Belgium
l.chiappi@inveaquaculture.com

**Introduction**
Effective microbial control in hatcheries is essential for achieving predictable and consistent outcomes. In production facilities, proactive microbial management, robust biosecurity measures, and thorough cleaning and disinfection protocols create a controlled environment that minimizes the risks of opportunistic bacteria entering or dominating the system.

Our study focuses on microbial management in the live food sector using EG SEP-Art® D-FENSE and a CIP (clean-in-place) agent to enhance biosecurity in the Artemia sector. The CIP agent is used initially to remove bacterial biofilm, reducing the microbial population in the tank. This step aids D-FENSE technology in controlling bacterial growth in the hatching and enrichment tank, ensuring consistent production of high-quality live food both nutritionally and microbially.

**Materials and methods**
Artemia cysts were hatched for 20 hours at a temperature of 28±1°C, and a salinity of 38ppt. The pH of the hatching medium was maintained above 8.2 during the complete hatching cycle using 120ppm of NaOH (30%) as needed. Two treatments were tested:

1) EG SEP-Art® (INVE Aquaculture, Belgium)
2) EG SEP-Art® D-FENSE (INVE Aquaculture, Belgium)

After hatching, Artemia nauplii were harvested, rinsed, and restocked for 22-hour enrichment using Easy DRY SELCO (INVE Aquaculture, Belgium) in two 360 ppm doses, one at the start and another after 10 hours. Temperature was maintained at 27±1°C, pH above 7.5 with 0.5 $g.L^{-1}$ bicarbonate initially and 120 ppm NaOH as needed. Dissolved oxygen was kept above 100% using pure oxygen. Three treatments were tested:

A) Traditional enrichment using rinsed Artemia nauplii from EG SEP-Art® cysts without applying a CIP agent during enrichment (Tr A).
B) Traditional enrichment using rinsed Artemia nauplii from EG SEP-Art® D-FENSE cysts with CIP agent (Tr B): 150 ppm at the start (T24+0) and 150 ppm after 10 hours (T24+10).
C) All-in-one enrichment using Artemia from EG SEP-Art® D-FENSE cysts in the same tank with CIP agent (Tr C): 150 ppm added after 18 hours (T18) and another 150 ppm after 28 hours (T28).

The microbial quality of the hatching and enrichment medium was assessed using traditional plating methods on TSA (1.5% salt) and TCBS agar. Water samples were filtered to remove nauplii. The treatment's effect on the enrichment process was evaluated by FAME (Fatty Acid Methyl Ester) analysis of the nauplii at the trial's end.

**Results**
Using EG SEP-Art® D-FENSE cysts significantly enhances the efficient production of high-quality live food. Results showed a 3-log reduction in total bacterial load and a 4-log reduction in Vibrio load in the hatching medium 24 hours post-hatching.

The use of EG SEP-Art® D-FENSE cysts during hatching, combined with the application of the CIP agent during traditional enrichment practices (Tr B), resulted in a 3-log reduction in both Vibrio and total bacterial load compared to the control treatment (Tr A).

In the all-in-one enrichment procedure, bacterial levels remained similar to Tr B, indicating that EG SEP-Art® D-FENSE with the CIP agent effectively controls microbial development. This method eliminates the labor-intensive step of harvesting and cleaning from traditional practices.

*(Continued on next page)*

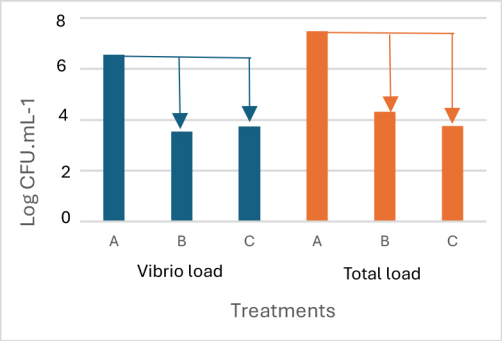

Figure 1. Vibrio load and Total bacterial load found in the enrichment medium after 24+22h & 40h for respectively the traditional way of enrichment (TrA and TrB) and the all-in-one procedure (Tr C).

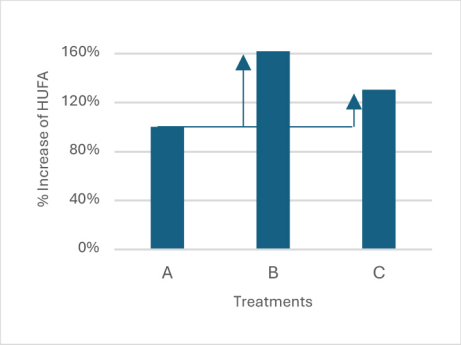

Figure 2. % of Increase in the total HUFA in Tr. B and Tr. C compared to Tr. A

Enhancing water quality with the CIP agent significantly improved enriched Artemia nauplii. HUFA content increased by 60% in Tr B and 30% in Tr C compared to Tr A (Figure 2). Lower bacterial levels likely reduce HUFA utilization and conversion. Improved water quality correlates with increased vitality, better water filtration, and enhanced nutrient uptake, thereby enhancing nutritional value.

**Conclusions**

These results demonstrate the effectiveness of combining EG SEP-Art® D-FENSE with the selected CIP agent in improving the microbiological and nutritional quality of Artemia. The study highlights the importance of strong biosecurity measures to enhance and standardize live food production.

Using EG SEP-Art® D-FENSE cysts with CIP agents (all-in-one treatment) streamlines hatchery operations by eliminating the intermediate harvest and rinsing step, reducing labor while maintaining high nutritional and microbial quality standards.

# UNVEILING ANTIVIRAL POTENTIAL OF PLANT EXTRACTS AGAINST VHSV IN RAINBOW TROUT

Veronica Chico*, Jenifer Criss Ellis, Aleida Marroqui, Celia Garcia-Quintanilla, Maria del Mar Ortega-Villaizán

*Instituto de Investigación, Desarrollo e Innovación en Biotecnología Sanitaria de Elche (IDiBE)
Universidad Miguel Hernández de Elche (UMH)
Elche, 03202, Spain
Email: vchico@umh.es

Aquaculture has emerged as a key solution to meeting the world's demand for fish feed over the last few decades. However, the sector faces significant economic challenges due to disease outbreaks. While chemical agents are commonly employed for disease management, their potential ecological impacts raise concerns. Plant extracts, with their inherent pharmacological properties, present a promising alternative. This study investigated the *in vitro and in vivo* antiviral activity of four plant extracts – *Vitis vinifera* (grapevine), *Rosmarinus officinalis* (rosemary), *Glycyrrhiza glabra* (licorice), and *Punica granatum* (pomegranate) – against viral hemorrhagic septicemia virus (VHSV) in rainbow trout. These plant species were selected based on existing evidence of their immunostimulatory or antiviral properties, with the aim of identifying novel antiviral compounds for aquaculture applications. The antiviral activity of plant extracts against VHSV was initially evaluated *in vitro* using the EPC cell line. Cytotoxicity assays established the working concentrations used in subsequent experiments. Then, the antiviral activity of the plant extracts, before or during the course of VHSV infection, were assessed and viral loads were evaluated by means of a focus forming units assay. *In vitro* results demonstrated that all tested plant extracts exhibited antiviral activity, reducing viral load by over 50% in all cases. Subsequently, an *in vivo* study was carried out on rainbow trout to evaluate the use of feed supplemented with plant extracts, analysing the immune response by RT-PCR and toxicity by haematological and biochemical techniques. The *in vivo* antiviral activity was further evaluated by challenging rainbow trout with VHSV and then feeding them with a diet supplemented with plant extracts and monitoring their survival for 20 days. The resulting survival rates exhibited variability depending on the specific plant extract administered, with certain extracts demonstrating superior outcomes. These findings suggest that the use of these plant extracts offers a potential alternative for controlling viral diseases in aquaculture.

# A SHADOW TWIN FOR MUSSEL-SEAWEED INTEGRATED MULTI-TROPHIC AQUACULTURE (IMTA) IN THE GALICIAN COAST (NW IBERIAN PENINSULA)

O. T. Chis[1 *], I. Fuentes-Santos[2], J. Pereira[1], J. Cremades[3], A. Pérez-González[3], E. García-Cardesín[3], J. Pintado[4], E. Balsa-Canto[1], X.A. Álvarez-Salgado[2]

[4] Marine Ecology and Resources Group, Institute of Marine Research (IIM-CSIC)
E-mail: ochis@iim.csic.es

This work focuses on the integrated culture of Mediterranean mussels (*Mytilus galloprovincialis*) and sugar kelps (*Saccharina latissima*) in the Ría de Ares-Betanzos (Galicia, NW Iberian coast), where the latter are cultured in longlines within a mussel raft polygon. Both seaweeds and mussels are low-trophic species which feed, respectively, uptaking seawater dissolved and particulate nutrients and, consequently, their culture does not imply any external food supply. For this reason, seaweed and bivalve aquaculture are among the most sustainable seafood production systems. However, they are also strongly dependent on local environmental conditions making them particularly vulnerable to environmental variability and associated risks such as extreme weather conditions and climate change.

In this context, the development of digital tools to model the growth of the species involved in the integrated culture system under variable environmental conditions is crucial, not only to evaluate and optimize the performance of implemented systems, but also as a site selection tool for the implantation of new mussel-seaweed farms.

We propose an integrated model coupling a high-resolution MOHID model, an individual-based net-production dynamic energy budget (DEB) model for mussels, and an individual based model (IBM) for seaweeds. The MOHID model, incorporates the effect of rafts and longlines in surface currents. The mussel DEB model, which simulates mussel growth under the variable environmental conditions of the culture area, incorporates a carbon-nitrogen (CN) module to estimate carbon, ammonia and nitrate release during growth. The IBM treats each seaweed as a distinct unit, with its own set of physiological and structural variables - such as biomass, nutrient content, and growth rate. These individual seaweeds interact dynamically with the local environment, responding to seawater conditions such as light availability, temperature, and salinity, as well as nutrients, including those released by the nearby mussel rafts in integrated aquaculture systems. This allows for a realistic simulation of heterogeneous growth patterns and nutrient cycling.

The proposed shadow twin can be used to test different culture strategies (seeding and harvest schedule, seeding density, spatial longline-raft configuration) under the variable environmental conditions of the culture area. Consequently, given the strong dependence of offshore IMTA on spatial planning and integrated coastal management, we provide a valuable asset to support producers and policymakers for the development of sustainable IMTA systems.

# ENVIRONMENTAL ENRICHMENT IMPROVES WELFARE OF JUVENILE ATLANTIC SALMON (*Salmo salar*)

**Introduction**

The breeding of animals for research purposes must meet high standards of animal welfare to ensure that experimental outcomes accurately reflect their biology. In fish, enriched environments (EE) support the expression of natural behaviours and promote positive animal welfare (PAW) (Jones et al., 2021). This is essential not only for obtaining valid and reproducible results but also for developing improved husbandry practices.

In Atlantic salmon (*Salmo salar*), early-life exposure to EE has been associated with increased brain plasticity and enhanced cognitive (Salvanes et al., 2013) function. In contrast, barren environments often lead to maladaptive behaviours and cognitive impairments, negatively impacting welfare and potentially compromising experimental data.

Previous studies have shown that EE improves the ability of fish to cope with stress and reduces the activation of the endocrine stress response. These benefits are linked to increased neuronal proliferation and behavioural flexibility, both key components of welfare. Serotonin (5HT) plays a central role in regulating anxiety, aggression, depression, and the integrated stress response. It also regulates neurogenesis and synaptic plasticity, both essential for learning, memory, and emotional regulation. Dysfunction in this system can quickly impair these functions (Backström & Winberg, 2017).

This study tested the hypothesis that early-life exposure to EE enhances stress resilience in juvenile Atlantic salmon by modulating serotonergic activity.

**Methods**

Atlantic salmon fry was randomly allocated into eight 700 litre tanks (n = 375 per tank, initial weight: 1 g), with a continuous water flow (900 l/h), 24-hour light regime, and temperature maintained at 12 °C. Four tanks were provided with structural EE consisting of a circular PVC grid (70 cm diameter) covered with artificial plastic plants, while the remaining four tanks served as non-enriched (NE) controls. Fish were kept under these conditions for 12 weeks.

Throughout the experiment, fish behaviour was monitored and novel object tests were conducted to assess emotional state. Three days before and 30 minutes after an acute stressor (5-minute chasing), 10 fish from each tank were euthanized using an MS222 overdose. Brain and blood samples were collected to analyse cortisol levels, brain serotonin content and absolute gene expression for markers related to stress, cognition, and serotonergic function.

**Results and discussion**

Fish reared in enriched conditions exhibited greater group cohesion, reduced neophobia, and more stable serotonin levels compared to NE fish. These results suggest that EE helps mitigate the effects of stress and promotes more positive emotional states.

The highest levels of serotonin (5HT) and its primary oxidative metabolite 5HIAA were found in the EE group. Following the acute stressor, significant increases were observed in 5HIAA levels and the 5HIAA/5HT ratio, indicating elevated serotonergic turnover. However, only NE fish showed a significant drop in 5HT levels post-stress, suggesting that EE fish maintained more stable serotonergic tone and were better equipped to cope with the stressor.

*(Continued on next page)*

Gene expression analysis revealed increased levels of markers associated with neuronal development and activity (*bdnf*, *ndf1*), cellular stress (*hsp90*, *hsp70*), and serotonin synthesis (*tph2*) in enriched fish after the stress event. Strong correlations between *bdnf* and both *hsp90* and *tph2* further support a link between neural plasticity and the stress response.

Overall, our findings demonstrate that early-life EE enhances cognitive function, stress resilience, and emotional state in juvenile Atlantic salmon. These outcomes highlight the importance of environmental enrichment in improving PAW in captive settings, ensuring that animals are free from negative experiences and have access to positive ones (Prentice et al., 2025).

## Introduction

Numerous investigations have highlighted frequent large-scale die-offs in olive flounder (*Paralichthys olivaceus*), largely linked to a variety of infectious agents. Key contributors to these episodes include *Miamiensis species*, which trigger scuticociliatosis; *Streptococcus species*, known for causing streptococcosis; viral hemorrhagic septicemia virus (VHSV), an easily transmissible viral invader; *Vibrio strains*, which bring about vibriosis; *Tenacibaculum* bacteria, implicated in gliding motility disorders; the protozoan *Cryptocaryon irritans*, which causes marine white spot illness (MWSD); and *Edwardsiella* bacteria, the source of edwardsiellosis. These organisms pose serious risks to fish farming operations, underlining the need for robust diagnostic systems and intervention measures to curtail disease progression and avoid substantial financial setbacks in the sector.

## Materials and methods

To explore the relationship between bacterial levels, water temperature, and extreme weather at aquaculture sites, a two-year field survey was carried out in Jeollanam-do and Jeju-do, Korea. This study evaluated how environmental and climate variables affect bacterial growth in fish farms. Based on continuous monitoring data, a novel water purification system (TSS-PRS) was developed and installed at a site in Jeollanam-do to test its real-world effectiveness in managing water quality. After deployment, both raw and treated water, along with cultured fish, were analyzed to determine the system's ability to reduce microbial contamination. Detection and quantification of ten critical pathogens were conducted using DNA extraction and real-time PCR techniques to ensure precise microbial assessment.

## Results

In untreated water, bacterial levels rose sharply in Jeollanam-do between July 12 and July 30, 2024—from $10.9\times10^3$ to $5.15\times10^4$ BQV $mL^{-1}$—coinciding with severe weather on July 16, including a peak temperature of 30 °C, 64 mm of rainfall, and wind speeds of up to 8.5 m $s^{-1}$ (Fig. 6e). This surge is likely linked to these meteorological extremes. In contrast, treated water showed a steadier pattern, with bacterial activity ranging from $3.00\times10^3$ to $7.68\times10^3$ BQV $mL^{-1}$ over the same period. Even during subsequent weather events—such as 45.4 mm of rain on September 21, 26.7 mm on October 22, and winds of 7.9 m $s^{-1}$ on November 26—bacterial levels in both treated and untreated samples stayed below $0.4\times10^3$ BQV $mL^{-1}$, indicating minimal impact.

## Introduction

Fish welfare is increasingly recognized as crucial for sustainable aquaculture, and minimizing stress is a key aspect of good welfare. New monitoring technologies are making it possible to observe fish behavior and well-being more closely than ever before. This collaborative study – involving experts from USB (Czech Republic) HCMR (Greece), SINTEF and NOFIMA (Norway), and CSIC (Spain) – explored how emerging tools like underwater video cameras, echosounders (sonar), and electronic biosensor tags can be used to monitor fish welfare. The aim was to identify common welfare indicators by detecting stress responses across multiple key European aquacultural fish species (Atlantic salmon, European seabass, and gilthead seabream) in different aquaculture systems (land-based tanks and net pens). By uniting efforts across institutions and species, the project provides a broad, high-level perspective on using technology to track fish well-being in real time.

## Materials and methods

Experiments were carried out in both controlled tank environments and marine open net pens to reflect common aquaculture settings. At each site, the team employed a multi-technology approach to monitoring the fish. Underwater video cameras were used to record fish behavior and schooling patterns, while an acoustic echosounder was deployed in the large net pen setups to track how the fish school distributed themselves in the water column. In the tank trials, some fish were fitted with data-logging tags (including acceleration sensors) that recorded their movement and activity levels. All three species (salmon, seabass, and seabream) were subjected to a mild, short-term stress challenge designed to mimic routine farm events – most often a crowding of the fish into a smaller space, and in the case of the net pens, the additional disturbance of a net cleaning procedure. These stressors were applied in a harmonized way across the different experiments so that results could be compared between species and environments. The combination of video, sonar, and tagging at each experimental site (as available) allowed researchers to capture complementary data streams and observe how each technology detected changes in the fishes' condition during and after the induced stress.

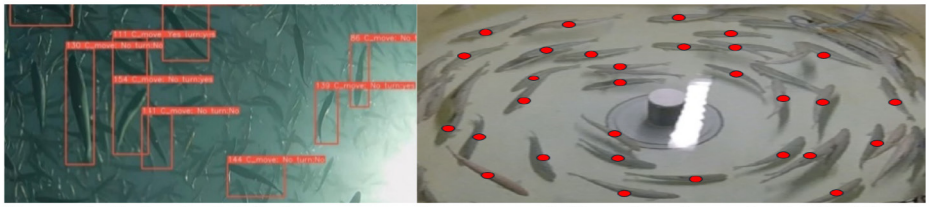

*Figure 1. Individual fish detection in the net pen (left) and in the tanks (right. The short tracks of the fish position serve as an individual fish behaviour parameter. Group-based behaviour parameters were then calculated from the individual-based parameters.*

*(Continued on next page)*

## Results

The monitoring tools successfully detected behavioral changes in the fish when a stress event occurred, although the specific responses varied by species and context. In general, when the fish were crowded or otherwise disturbed, the video recordings revealed noticeable shifts in behaviour – for example, altered swimming speeds, tighter schooling behaviour, or changes in preferred depth or location in the tank/net pen. The echosounder data from the salmon net pen similarly showed changes in how the school was distributed, such as fish moving away from the area of the net pen being cleaned, indicating avoidance behaviour. The sensor tags on individual fish in the tank trials captured spikes in physical activity corresponding to the moment of stress, confirming that those fish were reacting even if it was not immediately obvious on camera. Notably, all three species (salmon, seabass, and seabream) exhibited some form of stress response that these technologies picked up, but the magnitude and form of the response were species- and environment-dependent. For instance, the salmon in a net pen did not show as dramatic a change during crowding as salmon in a confined tank or as other species did, though even in the net pen subtle indicators (like slight increases in swimming activity under certain conditions) were observed. These findings highlight that species may display stress in different ways in different settings, underlining the importance of interpreting welfare indicators in context. Importantly, by using multiple methods together, the study was able to detect these varied responses more reliably – one method often confirmed or supplemented the observations of another, giving a more complete picture of the fishes' state.

## Conclusion

In summary, this study demonstrates the value of a multi-tech approach to monitoring fish welfare in aquaculture. Modern technologies such as video cameras, echosounders, and active tags each contribute unique insights into fish condition: video provides direct observation of fish behaviors and interactions, sonar offers a broad view of group distribution and movement in large enclosures, and sensor tags yield information on individual fish activity or physiology. These methods are complementary, and an integrated monitoring system that combines them can overcome the limitations of any single tool. For example, acoustic monitoring works well in large, sometimes opaque water environments like net pens, while cameras and tags are especially useful in smaller or clearer systems – using them together ensures that signs of stress do not go undetected. The collaborative, cross-species results of this project suggest that building a cohesive monitoring framework (where camera, sonar, and tagging data are used in concert) will enhance our ability to identify stress responses early and accurately. Such an integrated system could enable farmers and researchers to respond more quickly to welfare issues, ultimately improving fish well-being and health. The study's findings also emphasize that stress indicators are not one-size-fits-all; they depend on the species and context, so a flexible, multi-technology strategy is the most promising route to better fish welfare monitoring across diverse aquaculture conditions.

# BIG OR SMALL, ONCE OR MORE? OPTIMISING FEEDING FOR REDCLAW CRAYFISH

J. Claeyé, A. Plovie, H. Arnouts, T. Abeel

Odisee University of Applied Sciences
Aquaculture Education and Research Facility (Aqua-ERF)
Ottergemsesteenweg Zuid 713

E-mail: joachim.claeye@odisee.be

**Introduction**

The redclaw crayfish (*Cherax quadricarinatus*) is a freshwater crayfish native to northern Australia and southern Papua New Guinea. It has gained increasing attention in global aquaculture due to its fast growth, high market value, and adaptability to a wide range of environmental conditions.

As a species with omnivorous feeding habits, redclaw crayfish offer flexibility in diet formulation, making them ideal for sustainable aquaculture systems. Optimizing feeding strategies is essential to improve growth performance, feed efficiency, and overall production profitability.

Nutritional research on crustaceans for aquaculture often focuses on feed composition, mostly overlooking the effect of feeding methods. In this study we examine the effect of pellet size and feeding times per day on growth rate and survival of redclaw crayfish in recirculating aquaculture systems.

**Materials and methods**

Crayfish were kept at 27°C in 12 300L flat-bottomed rectangular tanks with a photoperiod of 16h light/8h dark. All tanks were equipped with brush shelters and connected to a RAS system with mechanical and biofiltration.

25 juveniles (1,11g ± 0,58g) were stocked per tank and fed one or four times per day with 2 or 6mm sized pellets (Carp EX, Aquabio) for 12 weeks. Restricted feeding was applied and daily feeding level evolved from 5% of total biomass (week 1-3) over 4% (week 4-6) to 3% (week 7-12). Each treatment was performed in triplicate.

Every three weeks, all live animals were counted and weighted. Survival percentage and Specific Growth Rate (SGR) were calculated.

**Results**

Specific Growth Rate is determined as the Average Body Weight increase percentage per day between stocking and the final sampling on week 12.

SGR was the highest in the tanks fed 4x per day with 2mm pellets ($2.37\%d^{-1} \pm 0.03\%d^{-1}$) and the lowest in the tanks fed 1x per day with 6mm pellets (2.11 %d-1 ± 0.02 %d-1). A Kruskal-Wallis test followed by post hoc Dunn's tests with Bonferroni correction only shows a significant difference between treatment 4x 2mm and 1x 6mm. However, the SGR in the tanks fed 1x per day with 2mm pellets and 4x per day with 6mm pellets also seem relatively high compared to the 1x 6mm treatment.

The dot plot below (left) shows the SGR for each tank of the four treatments on week 12.
Survival is determined as the percentage of animals per tank that survive between stocking and the final sampling on week 12.

Survival was the highest in the tanks fed 1x per day with 6mm pellets (76.00% ± 10.58%) and the lowest in the tanks fed 1x per day with 2mm pellets (60.00% ± 8.00%). However, no significant differences between treatments could be detected.

The dot plot below (right) shows the Survival for each tank of the four treatments on week 12.

*(Continued on next page)*

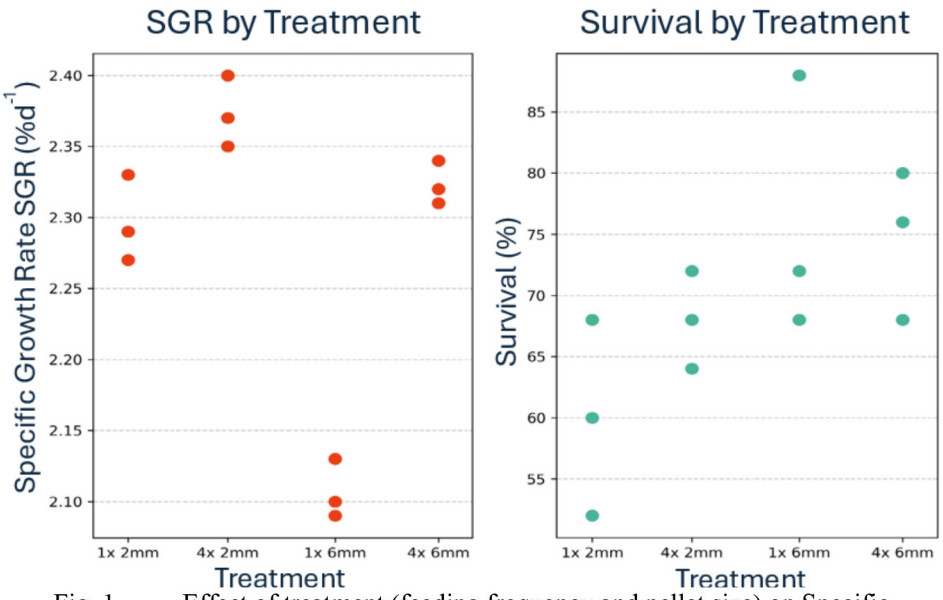

Fig. 1 Effect of treatment (feeding frequency and pellet size) on Specific Growth Rate (left) and Survival (right).

**Discussion**

Feeding four times per day smaller pellets, four times per day larger pellets, or once per day smaller pellets improves growth rate. Crayfish are opportunistic feeders and providing food multiple times may better mimic natural conditions, likely promoting more active and consistent feeding. Dividing the daily ration over multiple feeding times and/or more smaller pellets allows crayfish to digest and assimilate nutrients more efficiently, as they are not overloaded with a single large meal, supporting better growth.

Feeding only once per day larger pellets significantly decrease growth rate. In group settings, dominant individuals may monopolize feed when it is offered only once. A single daily feeding and larger but less pellets decrease the likelihood that subordinate or slower individuals get access to sufficient food, leading to lower average growth rate of the population. Moreover, less feeding times and larger but less pellets may result in less aggressive encounters between animals competing for feed, resulting in a higher survival of slow-growing individuals, again leading to lower average growth rate of the population.

Feeding methods are crucial in redclaw crayfish culture. For juvenile crayfish, multiple feeding events per day are preferred over one, preferrable with relatively small pellets. Although not proven in this experiment, pellet size and feeding frequency may also affect survival and should be adjusted based on the life stage and other culture parameters, such as stocking density and shelter type to reduce aggression and cannibalism, and to optimize production per tank.

# CHANGES TO ZOOXANTHELLAE DENSITY IN *Anemonia viridis* ACCLIMATED TO LOW-LIGHT AQUACULTURE ENVIRONMENTS

Alberto Coll*[1], Ana E. Ortiz-Maldonado[2], Ismael González-Ordóñez[1], Laura M. Pantoja-Echevarría[2], Marta Ramos-Barbero[3], Eva M. López-Fernández[2], Eva E. Rufino-Palomares[3], Amalia Pérez-Jiménez[2], Cristina E. Trenzado[1]

**Introduction**

In Spain, the high demand of snakelocks anemone *(Anemonia viridis*, Forsskål, 1775) for human consumption–along with the invasion of *Rugulopteryx okamurae*–has depleted populations of this species in the Andalusian coast, leading to an indefinite ban on its harvesting since 2023. Aquaculture production of this species has become relevant to help relieve natural populations from exploitation pressure in the region. Because they harbor photosynthetic dinoflagellates in their endoderm, *A. viridi*s requires a certain threshold of light intensity in order to perform adequately in aquaculture settings. However, intense solar radiation can induce oxidative stress from UV light exposure and from the increase in intracellular oxygen released by the symbionts (Richier et al., 2005). Moderating the amount of received light intensity could improve the performance of the animals in aquaculture settings (Coll et al. 2025).

Histological assessment can help detection of acclimation responses to different light conditions, which then can complement assessment of the physiological state of the animals (Coll et al., 2025). The goal of this study was to (1) characterize the histological structure of *A. viridis* body wall, and (2) study histological alterations of this structure associated to different light environments in aquaculture settings.

**Materials and Methods**

140 wild individuals of *A. viridis*, previously acclimated, were randomly distributed into two identical outdoor recirculation tanks (8 $m^3$) with three partitions each. Both tanks were exposed to natural photoperiod (12:12, L:D) and maintained at 21 ± 2 ºC, but one of them had a mesh cover that blocked approximately 99% of incident illuminance. After four weeks, tentacles from three animals per tank were dissected and fixated in Bouin's solution for 48 hours. Following histological processing, 5 µm longitudinal tentacle sections were stained with Masson-Goldner's trichrome. Finally, section micrographs were analysed with Image J to measure histological layers thickness, as well as density of symbiont cells per $\mu m^2$ of endoderm. Mean values were compared for control and shaded partitions using a t-test with a significance of $\alpha = 0.05$. Statistical analysis was performed with R 4.3.

**Results and Discussion**

*A. viridis* display the typical tri-layered structure found in cnidarians, composed of two tissular layers (ectoderm and endoderm) separated by extracellular matrix (mesoglea) (Figure 1). The outer ectoderm hosts an elevated number of cnidocytes of different types: spirocysts (adhesion-specialized cells with a coiled filament) stained brightly with acid fuchsine, while nematocyst (stinging cells with a straight filament) appeared stained with hematoxylin. The mesoglea, a collagen-rich extracellular matrix, stained intensely with anillin blue and displayed several cell nuclei belonging to amoebocytes (immune effector cells). Finally, the inner endoderm is dominated by symbiont cells, and features occasional secretory cells. Masson-Goldner trichrome was an effective staining technique to differentiate cnidarian body wall tissular and cellular components.

Comparison of each of the three layers' (ectoderm, mesoglea and endoderm) thickness revealed no significant differences between anemones kept at control conditions and in a shaded setup ($p = 0.412$, $p = 0.118$ and $p = 0.43$, respectively) (Figure 2), although there was a slight pattern of thicker mesoglea for shaded samples. However, symbiont cell density was found to be significantly higher in the shaded setup ($p < 0.05$). significantly higher in the shaded setup ($p < 0.05$).

*(Continued on next page)*

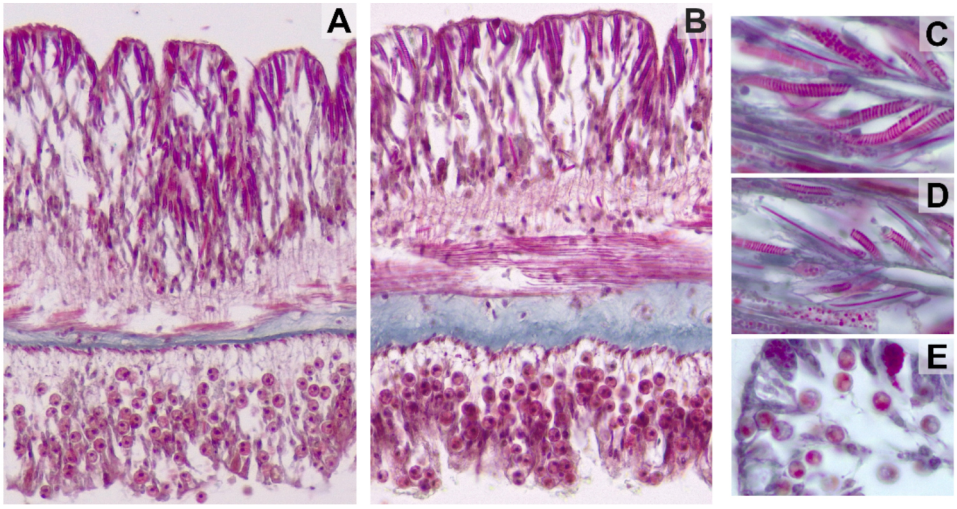

***Figure 1.*** Comparison of the tentacle structure of *A. viridis* in control (A) and shaded (B) conditions (40x). Detail of spyrocists (C), nematocysts (D) and zooxanthellae (E) (100x). Masson-Goldner stain, 5 µm sections.

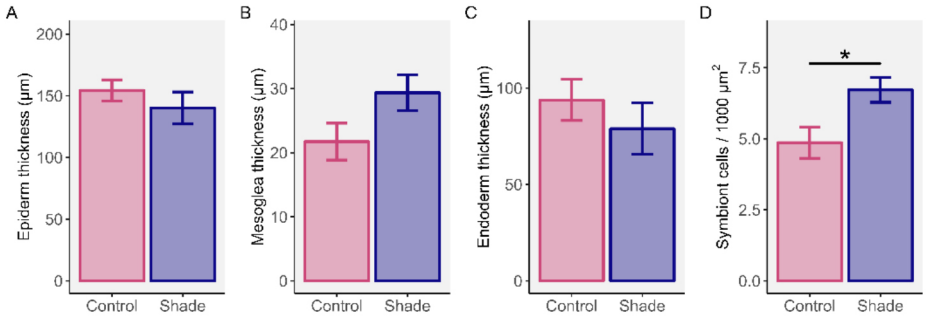

***Figure 2.*** Mean ± Standard Error thickness of epiderm (A), mesoglea (B) and endoderm (C), and symbiont density (D) in control or shade treatments. *: Significative differences between control and shade treatments.

Despite the general lack of histological alterations due to acclimation to different light environments, anemones displayed higher mean density of symbiont cells in their endoderm when acclimated to the shaded setup. This could be part of a compensation response to maintain a similar level of photosynthates flow into the animal host cells. Previous results found no alterations to oxidative status of *A. viridis* in shaded aquaculture conditions (Coll et al., 2025), suggesting that the setup minimized UV exposure while still allowing for sufficient light intensity for photosynthesis. The absence of bleached specimens also supports this hypothesis, but further studies of photosynthetic rates will be necessary to corroborate these results.

## Introduction

This study is part of the POLYRAS[1] project (Interreg GR), which aims to optimize the sustainable production of locally important fish species, such as pikeperch, through polyculture in recirculating aquaculture systems (RAS). Polyculture, a traditional practice in pond aquaculture, aim to exploit species complementarity to improve feed utilization and overall productivity (Thomas et al., 2020). Applied in RAS, polyculture may enhance feed efficiency, increase production, reduce labour and support animal welfare (Kolowski et al., 2014; Thomas et al., 2020; Penka et al., 2021; Amoussou et al., 2022).

This study evaluates, in a recirculating aquaculture system (RAS), whether co-culturing pikeperch (*Sander lucioperca*) with European catfish (*Silurus glanis*), a fast-growing bottom-feeding species, can offer some benefits compared to the monoculture of each species. Specifically, we investigated whether polyculture could maintain or enhance the growth of both pikeperch and catfish, improve overall tank productivity, make better use of uneaten food, and support species welfare. Results related to growth performance and tank productivity are presented in the present paper, while the aspects on feed valorisation and fish welfare will be addressed in future work.

## Material and Methods

The experiment was conducted in 7 x 1 m³ tanks supplied with water at 23°C in a recirculating aquaculture system (RAS) under a 12 h light / 12 h dark photoperiod. Three conditions were tested: pikeperch (*Sander lucioperca*) monoculture, European catfish *(Silurus glanis*) monoculture, and polyculture of both species (ratio 1:1). The initial stocking density was 8 $kg.m^{-3}$. Tanks in monoculture were run in duplicate and those in polyculture in triplicate. Initial mean body weights were 166.6 g for pikeperch and 181.8 g for catfish. Pikeperch were fed with floating pellets (Le Gouessant Percid Grower®, 52% proteins, 15% lipids) at maximal feeding rate, while catfish received sinking pellets (Coppens Silurus Pro®, 46% proteins, 19% lipids) at a restricted rate of 1.5% of biomass. Growth was assessed monthly by individually weighing 20 fish per species and tank, and total biomass was assessed at the start, mid-point, and planned end of the experiment. Here, we present preliminary results obtained after 134 days of the planned 174-day experiment. Data were analysed in R. Normality and homogeneity of variances were checked (Shapiro–Wilk and Bartlett tests); ANOVA with Tukey's post-hoc or Kruskal–Wallis with pairwise Wilcoxon tests were applied as appropriate ($P < 0.05$).

## Results

Survival rates were up to 97% for all batches.
For each species, Sspecific growth rates (SGR) were comparable between monoculture and polyculture: 0.77 for pikeperch in monoculture vs. 0.82 in polyculture and 1.22 for catfish in monoculture vs. 1.19 in polyculture. After 134 days, final mean body weights were 467 ± 16g for pikeperch in monoculture and 498 ± 14 g in polyculture; and 937 ± 35 g for catfish in monoculture and 897 ± 28 g in polyculture, No significant differences were detected between rearing conditions for either species ($P > 0.05$).

Food conversion ratio (FCR) and final biomass in polyculture were intermediate between those observed in both monocultures. FCR values were 1.05 for pikeperch monoculture, 0.92 for polyculture and 0.82 for catfish monoculture. At 134 days, mean total biomass per tank was 22.1 ± 1.8 kg for pikeperch monoculture, 31.3 ± 2.4 kg for polyculture and 41.2 ± 6.4 kg for catfish monoculture. No significant differences were found between conditions ($P > 0.05$).

*(Continued on next page)*

**Conclusions and perspectives**

Current results indicate that pikeperch–catfish polyculture in RAS can sustain favorable growth performance without compromising survival of both species. The last 40 days of production will be critical to confirm these performances and to validate the system's potential for enhancing feed utilization while maintaining fish welfare. To further evaluate the potential of the system, isotopic analyses will be used to identify ingested feed and confirm the hypothesis of the valorization of uneaten feed. For the assessment of fish welfare, we will examine fin condition in pikeperch and fin and barbels in European catfish, as well as (adapted from Policar et al., 2016). Additionally, cortisol levels in pikeperch scales will be measured to monitor physiological stress (adapted from Carbajal et al., 2018).

# CORRELATION BETWEEN SHELF-LIFE AND TOTAL VOLATILE BASIC NITROGEN (TVB-N) CONCENTRATION IN FARMED SEA BASS AND SEA BREAM STORED UNDER VACUUM (VP) OR IN MODIFIED ATMOSPHERE PACKAGING (MAP) AT 4 ± 2 °C

## Introduction

Fish meat is very perishable due to indigenous and microbial enzymes, which play a key role in spoilage and shelf life. The deterioration processes are rapid, progressive and strongly influenced by rearing, harvesting, slaughtering, handling, and storage conditions. Usually, the shelf life of gutted fish VP and MAP packaging stored at 4 ± 2 °C is approximately 9 days. The spoilage includes the production of short-chain peptides, amino acids and other non-protein nitrogen molecules, trimethylamine, TVB-N, sulfur compounds, lactic acid, acetic acid, ethanol, formaldehyde by tissue demethylase and formic acid, ketones and esters by bacterial enzymes. The aim of this work was to correlate the shelf life to TVB-N, concentrations to propose limits of sensory acceptability of farmed gutted sea bass (*Dicentrarchus labrax*) and sea bream (*Sparus aurata*) stored at 4 ± 2 °C.

## Materials and methods

Samples consisted of 3 different lots of farmed sea bass (*Dicentrarchus labrax*) and sea bream (*Sparus aurata*). The sea bass (474–578 g, 35 cm long), and the sea bream (404–440 g, 25 cm long) were bred in sea cages, collected, and slaughtered after a bath in water and ice. The fish were VP (-1.0 bar) and MAP (80% $N_2$, <1% $O_2$, 20% $CO_2$) by an Orved VM53 vacuum machine (Musile di Piave, Italy) and stored at 4 ± 2 °C until analysis. The packaging was a multilayer film consisting of polyethylene terephthalate (PET) with a thickness of 12 µm, aluminum with a layer thickness of 9 µm, nylon with a thickness of 15 µm, and polyethylene (PE) with a thickness of 75 µm. On day of sampling, three samples were collected and subjected to physico-chemical analysis (TVB-N, formaldehyde and formic acid; 1,2). Additional samples were subjected to sensorial analysis. Data were analysed using Statistica software version 7.0 (Statsoft Inc., Tulsa, OK, USA). The values of the different parameters were compared by a one-way analysis of variance, and the means were then compared using the Tukey's honest significance test. Differences were considered significant at $p < 0.05$. Sensorial analyses were performed by 20 non-professional and non-trained assessors (10 women and 10 men, representing food technology students and typical consumers). Sensory analysis was performed based on the triangle test (1). Three lots of 10 sea bass and sea bream samples, were evaluated by tasters who were asked to evaluate the influence of time 0 versus 15 days storage. In short, three samples, wrapped in aluminum foil, two of which were identical, coded with three-digit numbers, were given in a randomized order in a quiet room, and the assessors were asked to identify the different samples and their responses were collected on a paper card. The assessors were eventually required to provide an answer. Those who were able to distinguish between the samples were then asked to indicate which sample they preferred and/or whether both samples were acceptable. The statistical evaluation of the results was carried out according to ISO (3) and Stone and Sidel (4).

## Results

TVB-N concentration changed during storage ($p < 0.05$). At the beginning of storage, the TVB-N value of the tested gutted sea bass and sea bream was less than 14.0 mg N/100 g and then increased reaching values of 41.9 ± 0.2 and 41.5 ± 0.2 mg N/100 g, respectively (Table 1,2). These values indicate that a significative spoilage started some days before 15 days. Indeed, during 12 days of storage, TVB-N values were less than 34.0 mg N/100 g in both fish species; this value is considered acceptable according to the limit proposed by EC/1995 (5), which is 35 mg N/100 g. The level of formaldehyde, as expected, increased till 6 days of storage, due to the endogenous enzymatic activity ($p < 0.05$). Then it decreased as it was degraded to formic acid by tissue enzymes. Indeed, the concentration of the formic acid increased in both the fish species during all the storage up to 15 days ($p < 0.05$). However, both the formaldehyde and formic acid did not influence the acceptability of the fish because they were less than 20 mg/kg. No significative differences ($p > 0.05$) were observed between the two types of packaging.

Legend: TVB-N (total volatile basic nitrogen), mg N/100; formaldehyde and formic acid: mg/kg.

Among the non-professional subjects, all the assessors were able to distinguish the different samples by smell, a result that was statistically significant. The samples stored for 15 days were considered unacceptable. Comparing the samples stored for 0 and 12 days, the assessors were required to make a forced choice. Among the non-professional subjects, 7 out 20 assessors recognized the different samples ($p > 0.05$). According to the triangle test, the minimum number of correct responses needed to establish significance at $p < 0.05$ with 20 assessors is 11 (1,2). Despite they recognized the different samples, all the tested samples were considered acceptable. Similarly, the 12 assessors who did not correctly identify the different samples also rated all samples as acceptable.

## Conclusions

Considering the physico-chemical and sensorial analysis of both fish species, a shelf-life limit of 12 days was proposed, corresponding to a total volatile basic nitrogen (TVB-N) level less or equal to 35 mg N/100 g of product.

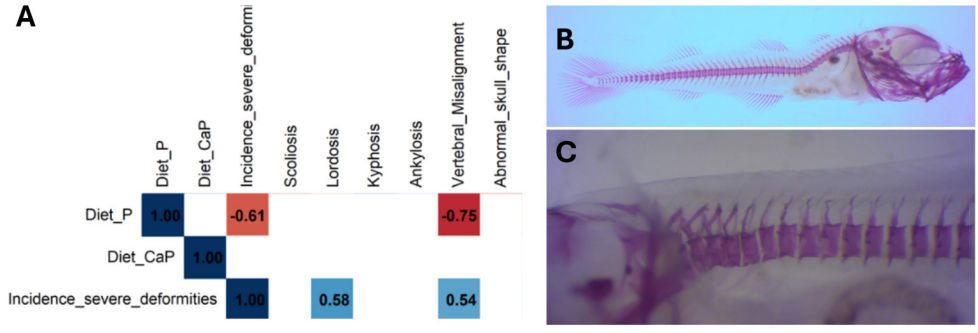
## Introduction

Atlantic cod microdiets need to be optimized, in order to reduce the high variability in growth performance, survival rates and incidence of skeletal deformities, commonly observed in hatcheries. Recent progress has been obtained with the use of alternative live prey in feeding protocols, and with novel microdiet formulations and technology for cod, in recent years. Different factors impact the incidence of skeletal deformities in fish larvae, including water temperature during early development, nutrition, and tank hydrodynamics. Among nutritional factors, phosphorus (P) and calcium (Ca) dietary levels, and their ratio, are usually considered as important to be optimized so to prevent skeletal deformities. The present study evaluated the impact of phosphorus and calcium dietary levels, and their ratio, on larvae performance and skeletal deformities of Atlantic cod.

## Materials and methods

Atlantic cod (*Gadus morhua*) larvae originating from NOFIMA AS (Tromsø, Norway) were randomly distributed in fifteen 200 L tanks at 3 days after hatching (DAH) and kept until 50 DAH (trial end), at the NTNU Sealab facilities (Trondheim, Norway). The tanks were equipped with a self-cleaning system and automated feeders. The light regime was 24h and temperature ranged from 7.1 to 12.3°C. All tanks were fed with the same live feed protocol. Fish were initially fed with enriched rotifers, and using green-water technique. The enrichment used was ENRico (Sparos Lda, Olhão, Portugal), with rotifers being enriched for 8 hours with 2 doses of 0.12 g/million rotifers. To obtain green-water conditions Phytobloom RAS (Necton SA, Olhão, Portugal) was used, by adding 6g/tank/day, in order to keep an algal density of 200000 cell/mL. At day 15 unenriched Artemia (strain AF, INVE, Dendermonde, Belgium) was introduced, and co-feeding of Artemia and microdiets occurred from 15-29 DAH. Enriched Artemia was not used in the present study. The 5 microdiets tested were fed alone from 30 DAH onwards. All diets were produced at SPAROS (Olhão, Portugal) by low-shear extrusion. Two levels of P (1.5 and 2.0%, feed basis) and 3 Ca:P ratios (0.4, 0.6 and 0.8) were tested in the following combinations: P2/0.4; P2/0.6; P2/0.8; P1.5/0.4; P1.5/0.6. Larvae were sampled for growth, Ca and P contents, and skeletal anomalies (staining with alizarin red S). Results were analysed using univariate statistics by fitting linear models, followed by two-way ANOVA (2W-ANOVA) with Type II sum of squares to test for main effects and interactions, as well as principal component analysis (PCA) and correlation analysis.



**A.** Correlation coefficients for significant linear regressions ($p<0.05$).between severe deformities and dietary levels of phosphorus, and Ca:P ratio, over the 15 tanks used in trial. Only significant differences are shown. **B.** Atlantic cod larvae with scoliosis**. C.** Atlantic cod larvae with vertebral misalignment.

*(Continued on next page)*

**Results**

Dietary P and Ca:P (2W-ANOVA, $p>0.38$) had no impact on growth parameters (dry weight, total length) at 30 or 50 DAH ($p>0.65$). Moreover, no interaction was detected between dietary P and Ca:P impact on growth ($p>0.17$). Relative growth rate until 50 DAH was around 9.5%/day. Mortality at 50 DAH was significantly lower ($p=0.03$) at dietary P of 1.5% (6.0%) compared to 2.0% (6.9%). The incidence of severe skeletal anomalies was significantly higher ($p=0.03$) at dietary P of 1.5% (47.24%) compared to 2.0% (25.56%); This lower incidence of severe skeletal anomalies at 2.0% compared to 1.5% dietary P was mostly driven by vertebral misalignment (6.2% vs 17%) and lordosis (4.5% vs 7.%). Other severe anomalies observed were scoliosis (6% average in all treatments), ankylosis (8%), and to a lesser extent abnormal skull shape (1.9%), and kyphosis (0.7%). Dietary P had a highly significant effect ($p<0.002$) on fish content of P, Ca and the Ca:P ratio. Dietary Ca:P ratio had also a significant effect ($p<0.04$) on fish content of Ca and the Ca:P ratio, but not on P contents ($p=0.28$). No significant interactions ($p<0.05$) were observed between Dietary P, and Ca:P ratio, on the mineral contents of Atlantic cod.

**A.** Correlation coefficients for significant linear regressions ($p<0.05$).between severe deformities and dietary levels of phosphorus, and Ca:P ratio, over the 15 tanks used in trial. Only significant differences are shown. **B.** Atlantic cod larvae with scoliosis**. C.** Atlantic cod larvae with vertebral misalignment.

**Conclusions**

Dietary Phosphorus (1.5 to 2% of feed) and Ca:P ratios (0.4 to 0.8) have no impact on growth of Atlantic cod. However, to improve skeletal mineralization, and reduce skeletal anomalies, a dietary Phosphorus level of 2% of feed is recommended. Nevertheless, Ca:P ratio seems to have little impact on skeletal mineralization and skeletal of Atlantic cod. These results highlight the potential of tailoring microdiets for Atlantic cod larvae may bring to improvement of larval and juvenile quality.

# FIRST APPROACH TO *Elasmopus rapax* CULTURE (Crustacea, Amphipoda): LIFE HISTORY TRAITS AND HABITAT PREFERENCE UNDER LABORATORY CONDITIONS

T. Conde-Crespo*, A. Badajoz-Rodriguez, N. Casado-Coy and V. Fernandez-Gonzalez

Department of Marine Sciences and Applied Biology
University of Alicante
Carretera San Vicente del Raspeig s/n

E-mail: tomas.conde@ua.es

## Introduction

In recent years, amphipods have gained increasing relevance in the fields of aquaculture due to their key role in marine food webs, high reproductive efficiency, and potential as a component of IMTA systems (Fernandez-Gonzalez et al. 2018). Indeed, amphipod feeds might be used in aquaculture to replace *Artemia* in different nursery feeding regimens, as a fishmeal substitute in aquafeeds, or as either live or frozen feed for fish and crustaceans (Herawati et al. 2020, Vargas-Abúndez et al. 2020).

*Elasmopus rapax* is a cosmopolitan marine amphipod found in a wide range of coastal environments, particularly rocky and vegetated bottoms. Its frequent occurrence in fouling communities and tolerance to variable conditions make it a promising candidate for experimental studies.

This study presents a first approach to assessing the feasibility of the culture of *E. rapax* under laboratory conditions, focusing on key biological aspects such as average fecundity and habitat preferences.

## Materials and Methods

Individuals of *E. rapax* were collected from fouling communities of an aquaculture facility located in the western Mediterranean (San Pedro del Pinatar, Murcia). In the laboratory, they were maintained in 10 L aquaria with filtered seawater, controlled temperature (22–25 ± 1 °C) and fed daily with feed pellets and live diet (copepods, Artemia, rotifers and phytoplankton). Two main experiments were conducted:

1. Fecundity: Ovigerous females were selected, and the number of eggs was quantified under a stereomicroscope.
2. Habitat preference: Five types of substrates were offered: (A) artificial algae resembling *Ulva*, (B) plastic bioballs placed on the bottom, (C) ceramic bioballs on the bottom, (D) floating plastic bioballs, and (E) a motorized water filter. The distribution of individuals across the different substrates was recorded after 48h of acclimation and the individuals were counted twice per day for 3 weeks.

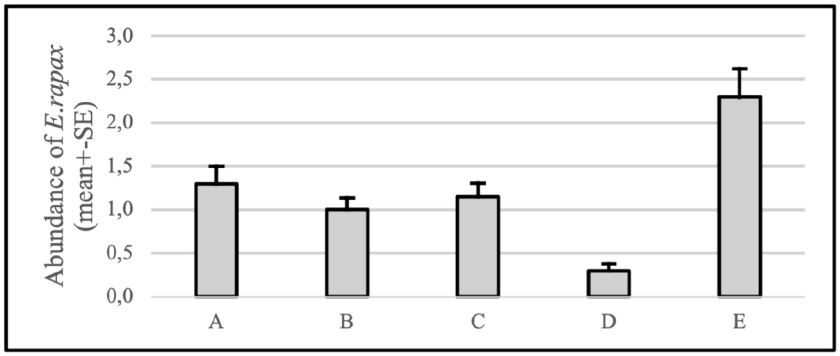

*Fig 1:Amphipods (*E. Rapax individuals*) observed in the different habitats (mean ± SE). (A) artificial algae resembling* Ulva*, (B) plastic bioballs placed on the bottom, (C) ceramic bioballs on the bottom, (D) floating plastic bioballs, and (E) motorized water filter.*

*(Continued on next page)*

**Results and Discussion**.
This study is the first reporting a culture system for the amphipod species *E.rapax,* which has been satisfactorily maintained for more than one month. Preliminary fecundity results (11.9 ± 4.3 eggs per female) fall within the range reported for other marine amphipod species, being fecundity often positively correlated with the female's body size (Vargas-Abúndez et al., 2020).

Regarding habitat preferences, the most frequently used substrate was the E (2,29±0,33), followed by A (1,29 ± 0,2) and C (1,15 ± 0,16). B (1,00 ± 0,13). This distribution suggests that structural complexity and substrate are related to algae and rocky habitats and high hydrodynamism, playing a significant role in microhabitat selection for this species.

Based on our results, *E. rapax* is a species with promising potential in aquaculture as a food source for fish and crustaceans due to its manageable nature and possible nutritional value. However, further research is needed to optimize rearing conditions and assess its reproductive and nutritional performance.

**Acknowledgments**
We would like to thank Mateo Ballester and the staff of the PISCIALBA fish farms who allowed access and helped in the study. We are also grateful to our colleagues Lucía Quiles, Bárbara Llorca, and Nickolás Fernández for their valuable assistance provided during this study. This study is part of the project *"Culture and use of marine invertebrates in aquaculture systems with low environmental impact (CAMBIA)"*, carried out with the support of the Biodiversity Foundation (Spanish Ministry for Ecological Transition and the Demographic Challenge) through the Pleamar Programme, and co-financed by the European Maritime, Fisheries and Aquaculture Fund (EMFAF).

# STAKEHOLDER ENGAGEMENT AND HEALTH-RELATED METRICS FOR SUSTAINABLE AQUACULTURE KEY SUCCESS INDICATORS (KSIs) IN AQUACULTURE

Maria Constenla[1]*, Ivona Mladineo[2,3], Anna Holčáková[2], Francesc Padrós[1]

[1]Universitat Autònoma de Barcelona. Spain
[2]Institute of Parasitology, Biology Centre CAS. Czech Republic
[3]IMAS, University of Tasmania. Australia

**Introduction:**
Success Indicators (SIs) are measurable values used to track progress toward specific objectives, while Key Success Indicators (KSIs) are a subset of these—metrics that are directly relevant and signal whether meaningful progress or failure is occurring. Objective, data-driven evaluation using scientifically validated methods is essential for credible success assessment, especially over time. This concept, originally applied in the context of public health (e.g., measuring the impact of COVID-19 vaccination programs), has also been adapted specifically to health and welfare aspects of aquaculture through the One Health framework (Stentiford et al., 2020), where indicators were developed across ecological, societal, and organismal dimensions. Building on this approach, the Cure4Aqua project aims to define and implement tailored KSIs in five key areas of fish health and welfare: vaccines and vaccination, epigenetics, disease control, diagnostics, and welfare. Each area will establish its own set of indicators through dedicated process groups, ensuring a comprehensive and systematic evaluation framework across the project's objectives.

**Materials and Methods**
The methodology for identifying KSIs within the Cure4Aqua project followed a two-phase, participatory approach.

In the first phase, an internal brainstorming session was held with members from each Work Package (WP) to generate preliminary ideas for relevant SIs and KSIs in key areas of fish health and welfare. These initial concepts served as the basis for structured discussions with external experts.

The second phase involved the formation of Process Groups (PGs) composed of selected external experts from academia, industry, public administration, and EU reference centres. Using a modified Delphi methodology, two PG rounds were conducted with an inter-round questionnaire. In the first round, experts engaged in a guided online brainstorming session to propose and discuss potential KSIs, assessing their relevance, feasibility, measurability, and data availability. Additional internally developed KSIs were also presented for feedback. Following this, a questionnaire was circulated to all experts to individually evaluate the proposed KSIs across multiple criteria (e.g., data robustness, usefulness, objectivity) and assign an overall score. The results were analysed and presented during the second PG round, where experts collectively validated and prioritized the final KSIs. This process led to the consensus-based selection of the top five KSIs to assess the effectiveness of the five key areas on aquaculture.

**Results:**
Preliminary results focusing on two of the main areas, **vaccines** and **welfare**, are presented and discussed.

Five KSIs were validated as the most relevant to assess the progression of fish vaccination in aquaculture: availability of vaccines on the market (KSI 1), number of diseases covered included in farm vaccination plans (KSI 2), decrease in disease incidence on farms (KSI 3), cost-effectiveness of vaccination strategies (KSI 4), and the number of pathogens/diseases covered per vaccine (KSI 7). Together, these indicators provide complementary insights into vaccine efficacy, effectiveness, and technological advancement in aquaculture health management.

For welfare, all proposed KSIs contribute to understanding welfare progress at different levels. However, the most highly valued indicators were the following: products certified for welfare (KSI 10), training for national competent authorities (KSI 6), and availability of welfare guidelines in a country (KSI 9). Although KS6 and KS9 are less directly connected to on-farm practices, these indicators highlight market demand, farm willingness for welfare certification, governmental interest, and regulatory engagement. A balanced mix of policy, practice, and market indicators is essential, along with clearer definitions and improved data access.

*(Continued on next page)*

**Conclusions:**
Preliminary results highlight key indicators for both vaccination and welfare in aquaculture. For vaccination, five KSIs were identified as most relevant, offering insights into efficacy, disease coverage, and economic impact. In terms of welfare, the most valued indicators reflect market certification, governmental commitment, and regulatory progress, pointing to the importance of aligning stakeholder efforts across the policy, production, and consumer spheres.

# ENHANCING FEED INTAKE, GROWTH, AND WELFARE IN EUROPEAN SEABASS (*Dicentrarchus labrax*) FARMING: NOVEL AQUAFEED ADDITIVES FOR A SUSTAINABLE AQUACULTURE

F. Conti*, M. Zarantoniello, M. Antonucci, E. A. Belfiore and I. Olivotto

Department of Life and Environmental Sciences
Marche Polytechnic University
via Brecce Bianche

E-mail: f.conti@pm.univpm.it

## Introduction

One of the primary goals of modern aquaculture is to develop sustainable aquafeeds, largely focusing on alternative protein sources to replace traditional marine-derived ingredients. Meals derived from plant, livestock, insects and microbial sources, are the main alternatives currently employed, that however often result in lower diet's palatability. In fact, the off-flavour substances present in these ingredients often affect aquafeeds attractiveness, depressing fish feed intake, eventually having negative consequences for growth and welfare. Additionally, the resulting feed wastage derived from uneaten feed has side effects on both the farm's economy and the environment. In fact, not ingested feed remains in wastewater outflows and thus can contribute to the eutrophication of aquatic ecosystems, representing a direct financial loss as well.

To improve aquafeed palatability, marine-derived feed attractants are regularly included in aquafeeds. Particularly, meals derived from shrimp, anchovy, and squid are well-recognized feed attractants, but due to their natural origin they present both unsustainability issues and highly variable attractiveness. In fact, their attractive effect depends on their harvesting location, the raw material quality and composition, the freshness, and processing methods, posing sustainability concerns and fluctuations in the product availability. The current alternative solution is represented by a limited number of molecules, such as mixture of free amino acids, nucleosides, and nucleotides, or substances such as betaine and taurine, that can be used as feed attractants. Particularly, among these substances, amino acids have been shown the strong attractive effects, although the limitations and disadvantages of their use as feed attractants are well-known. In this context, synthetic flavours are emerging as a promising and sustainable alternative to conventional feed attractants, obtained through standardized processes. Preliminary studies conducted throughout the zebrafish life cycle (*Danio rerio*) demonstrated that the dietary supplementation of attractive synthetic flavours had positive effects on appetite stimulus, feed ingestion, reward pathways and, consequently, on the growth of fish. Zebrafish is widely recognized as an optimal model for finfish nutrition research, and preliminary findings in this species can serve as a foundation for further studies in farmed fish.

In this regard, the aim of the present study was to test the effectiveness same synthetic flavours previously tested in zebrafish, on European seabass (*Dicentrarchus labrax*), during a 90-day feeding trial, evaluating the fish physiological responses. The European seabass is a strictly carnivorous species with a high market value and of particular importance in the aquaculture sector of the Mediterranean region. The application of synthetic flavours as feed attractants can help reduce feed wastage and improve farm's productivity. This approach also supports the shift toward more sustainable and eco-friendly practices in aquaculture.

## Materials and Methods

*Experimental diets.* Two attractive (F1, cheese; F2, caramel) and one repulsive (F3, coconut) flavours, previously tested throughout zebrafish life cycle, were produced by To Be Pharma S.r.l. (S. Egidio alla Vibrata, Teramo, Italy). The selected flavours were then included in a commercial diet for European seabass (Ecoprime, Veronesi, VR, Italy), rich in land animal proteins (LAPs). Then, four experimental diets were prepared starting from the commercial CTRL diet by adding Propylene Glycol (basic solvent used for flavours' production), F1, F2, and F3 flavours (named PG, F1, F2, or F3 diets, respectively). The PG and all the flavours were added at 1% (w/w) to the CTRL diet.

*(Continued on next page)*

*Experimental design.* Five hundred and forty European seabass juveniles (initial body weight: 72.48 ± 8.04 g) were initially acclimated for two weeks. At the end of acclimation period, fish were randomly divided into six experimental groups (in triplicate) as follows: (i) CTRL group, fish fed the CTRL diet; (ii) PG group, fish fed PG diet; (iii) F1 group, fish fed F1 diet; (iv) F2 group, fish fed F2 diet; (v) F3 group, fish fed F3 diet; (vi) ROT group, fish fed the two attractive diets (F1 and F2), each administered singularly in a weekly rotation scheme, to avoid a possible olfactory receptors adaptation in response to a long-term stimulation. The duration of the feeding trial was 90 days during which fish were hand-fed the experimental diets at 1.5% of body weight, daily monitoring the feed consumption. At the end of the feeding trial, all the fish were euthanized and then individually weighted.

*Analyses.* Biometric data were used to calculate the zootechnical parameters, and the daily feed intake was evaluated. In addition, samples from brain, liver, and distal intestine, were collected for: i) histological analyses in liver to determine the hepatic lipid and glycogen deposition and in distal intestine to verify eventual alterations or signs of inflammation; ii) molecular analyses to evaluate the gene expression of markers involved in fish brain reward system (*drd3*), serotonergic system (*5ht1a*), and immune response (*il1b*, *il10*, *tnfa*).

**Results and Discussion**

The PG and all the tested synthetic flavours had no adverse effects on liver and distal intestine, as widely demonstrated by the histological analyses. However, fish fed caramel and coconut diets showed an upregulation of immune-related markers in distal intestine, despite the clear absence of inflammatory process evidenced by the histological analyses. However, the various roles of interleukins may explain result inconsistencies, highlighting the need for more research on how synthetic flavours affect cytokine gene expression. Despite this, fish fed F2 (caramel) diet showed a higher feed intake, confirming, even in this species, the attractive effectiveness of the caramel flavour, as already demonstrated in zebrafish. This led to direct consequences on the amount of energy available for fish to support growth performance and storage of nutrients. In fact, caramel group showed the highest weight gain and growth rates and exhibited a significantly higher fat percentage in the liver. Finally, the positive modulation of monoaminergic pathways in F2 group may contribute to the hedonic value of the diet and the desire to consume feed, driven by reward sensation.

Overall, the caramel flavour notably improved feed palatability, enhancing its intake and fish growth, highlighting the role of sensory cues in feeding motivation. This study confirmed the potential of synthetic flavours to enhance aquaculture practices in a sustainable and cost-effective approach for the sector.

# CIRCULAR AQUACULTURE: WASTE VALORIZATION FROM INSECT REARING FOR SUSTAINABLE AQUAFEED AND AGRICULTURAL APPLICATIONS (ACInA PROJECT)

F. Conti*, M. Zarantoniello, E. A. Belfiore, S. Nisar, D. Caterino, A. Eusebi, F. Fatone, F. Faccenda, I. Olivotto

E-mail: f.conti@pm.univpm.it

**Introduction**

Aquaculture is a critical contributor to the global economy, with an estimated production of 88 million tons of aquatic animals in 2020. As the fastest-growing sector within animal production, it holds significant potential for expansion in the coming decades. However, the development of innovative and sustainable aquafeed formulations remains a crucial factor in supporting its continued growth and long-term viability.

Chitin, the second most abundant polysaccharide in nature after cellulose, has emerged as a promising additive in aquafeeds, with potential to improve growth, intestinal health, and immune response of aquatic organisms. Traditionally, meals derived from shrimp and yeast have been the main sources of chitin in aquaculture feeds. However, the increasing interest in insect meal as a component of aquafeeds has positioned insects as a promising alternative protein source. Notably, insect farming generates biological by-products such as pupal exuviae and the exoskeletons of deceased adults, which are rich in chitin. Developing alternative processing strategies for these waste materials could enable the production of value-added products, potentially serving as nutritional supplements in the diets of various fish species. Rainbow trout (*Oncorhynchus mykiss*) is the most extensively cultivated freshwater species in both Europe and Italy, ranking highest in terms of production volume and economic significance. Despite its prominence, efforts to improve the sustainability of rainbow trout aquaculture remain a central focus of current research. In addition to the ongoing need for optimizing feed formulations, it is well-recognized that aquaculture operations generate considerable amounts of organic waste, including uneaten feed, fish faeces, and processing by-products. Effective waste management is therefore essential to reducing environmental impacts and improving resource efficiency.

In this context, innovative strategies such as waste valorization and the implementation of circular economy models are being investigated to mitigate pollution, enhance the recovery of valuable resources, and produce value-added products from aquaculture residues.

Within this context, the ACInA project adopts circular economy and zero-waste principles by linking aquaculture, insect farming, and agriculture to develop and validate waste valorization processes. This integrated strategy aims to improve sustainability, reduce environmental impact, and enhance resource efficiency across sectors.

Insects will be reared on substrates made from agri-food by-products, enabling the sustainable conversion of waste into high-value biomass. Insect-derived by-products will be used to formulate functional aquafeeds, while aquaculture waste (e.g., fish viscera and faeces) will be repurposed into compost and fertilizers for agricultural use.

Specifically, chitin extracted from insects will be incorporated into rainbow trout diets to evaluate its effects on fish growth and welfare.

**Materials and Methods**

In detail, the project focuses on: i) collecting exuviae and deceased adult specimens of the Black Soldier Fly (*Hermetia illucens*) reared on agricultural waste; ii) extracting chitin – alone or with macronutrients from both larvae and adult specimens – to formulate functional feeds for rainbow trout (*Oncorhynchus mykiss*); iii) revalorizing aquaculture waste into organic-based fertilizers for soil conditioning in agriculture, supporting the complete closure of the production cycle.

*(Continued on next page)*

*Exuviae collection.* Initially, agricultural organic by-products will be used as rearing substrate for *Hermetia illucens*, within a vertical farming system. During the larval stage, insects will be kept at environmental parameters suitable for their growth: temperature at 27-28 °C, humidity 70% and no light. At the end of insects' reproduction cycle, larvae, exuviae alone, and deceased adults will be collected, dried, and grinded through a mill. The recovered products will then be used for the preparation of trout experimental diets.

*Experimental diets.* Starting from a commercial diet specific for rainbow trout, which will be used as Control diet (C –), four experimental diets will be obtained: (i) C+ diet, (control diet + 5% w/w of larvae insect meal); (ii) E diet, (control diet + 1% w/w insect exuviae); (iii) A diet, (control diet + 1% w/w adult insect meal).

*Experimental design.* Three hundred rainbow trout (initial body weight: 100-120g), will be initially acclimatized for a minimum of two weeks at the experimental fish center (Fondazione Edmund Mach; Centro di Trasferimento Tecnologico, San Michele a./A., Italy). After this period, fish will be divided into 12 open circulating tanks (800L; three tanks per experimental group), according to the four experimental diets, obtaining four experimental groups. Fish will be hand-fed the experimental diets 5 days per week from 2% to 1.5% of the biomass adjusting it by mean body weight. At the end of the feeding trial, (upon reaching commercial size, 500g, 16 weeks) 5 fish per tank (15 per experimental group) will be weighted and zootechnical parameters will be measured.

*Analyses.Biometric and zootechnical indexes:* (i) growth performances calculating the specific growth rate (SGR%), and weight gain (WG); (ii) feed conversion ratio (FCR), to evaluate feed efficiency; *histological analyses* for hepatic lipid and glycogen deposition, and in distal intestine, histopathological indexes; *Molecular biology* expression of genes involved in immune response (*il1b*, *il10*, *tnfa*) and on chitin digestion (*chia*) assessed in distal intestine and stomach, respectively.

Finally, waste matter from reared fish (mainly faeces and uneaten feed) will be collected to be used for the other tasks of the project (Department of Science and Engineering of Matter, Environment and Urban Planning – SIMAU). Aquaculture wastes will be characterized in terms of carbon and nutrient (nitrogen and phosphorus) content will be subjected to co-composting processes to obtain high-quality fertilizer.

**Results and Discussion**

ACInA project adopts circular economy and zero-waste principles by linking aquaculture, insect farming, and agriculture to develop and validate processes for waste valorization. This integrated strategy aims to improve sustainability, reduce environmental impact, and enhance resource efficiency across sectors.

In this context chitin, a biopolymer derived from insect exoskeletons reared on vegetable by-products, was investigated for its potential benefits when included in rainbow trout diets. Its incorporation may enhance gut health, boost immune response, and improve overall growth performance. To better understand the role of this biopolymer laboratory analyses have been adopted and integrated. Simultaneously fish waste will be subjected to co-composting processes to obtain high-quality fertilizers to be used in agriculture. This will allow the project to be completely circular.

The approach will include interdisciplinary aspects, integrating the research areas of Chemical, Environmental and Sanitary Engineering and Biology. Integration and validation of mass and energy balances will be conducted to evaluate the efficiency, sustainability, and scalability of the proposed technological solutions through Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) analyses. Finally, dissemination of all the results will include reports, scientific and informative articles, and participation in national and international events.

ACInA project (Bando Ricerca e Sviluppo 2023/24 Fondazione Caritro project N° 2023.0598) is supported by Fondazione Cassa di Risparmio di Trento e Rovereto.

# BENCHMARKING SUSTAINABILITY IN AQUACULTURE: INSIGHTS FROM IRELAND's INAUGURAL SECTORAL REPORT

R. Cooney, E. Jackson, J. Dennis, C. Morrison

Bord Iasciagh Mhara (BIM)
Dublin, Ireland
Email: ronan.cooney@bim.ie

**Introduction**
In response to growing global seafood demand and the imperative for sustainable food systems, Bord Iascaigh Mhara (BIM), Ireland's Seafood Development Agency, has published its first sustainability report on the Irish aquaculture sector. Sustainability reporting in aquaculture is essential for tracking progress, identifying areas for improvement, and informing policy and investment decisions. Sustainability reports provide transparent, science-based data that enable industry, stakeholders, regulators, and the public to assess environmental, economic, and social performance—ensuring that growth in the sector aligns with national and EU sustainability objectives (EC, 2019, 2020, 2021, DAFM 2023). This report establishes a baseline assessment of the sustainability performance of the Irish salmon, rope mussel, and oyster farming sectors, using data from 2017 to 2019.

The initiative aims to supports both the European Union's Strategic Guidelines for the Sustainable Development of EU Aquaculture (2021–2030) (EC, 2021) and Ireland's National Strategic Plan for Sustainable Aquaculture Development (DAFM, 2023).

**Materials and Methods**
The evaluation framework spanned four key pillars: environmental impact, economic performance, social contribution, and innovation. Data collected as part of national annual surveys and other national reports provided background information which allowed for analysis and investigation across the four pillars. In total 24 impact indicators were used as part of the analysis Environmental indicators assessed greenhouse gas emissions, feed resource efficiency, edible protein energy return on investment, meals produced and spatial use. Economic indicators included Gross Value Added (GVA), running cost to turnover ratio, labour productivity, and net profit. Social impacts were assessed through employment multipliers, workforce demographics, and gender diversity. Innovation was measured by the adoption of new products, processes, and organisational forms.

**Results**
Environmental analyses demonstrated that Irish aquaculture operates as a low-carbon, resource-efficient sector, producing over 154 million meals annually. Edible protein energy return on investment also demonstrated strong results, indicating efficient returns. Year-to-year variability in environmental performance was noted but overall sustainability indicators remain strong. Economically, while GVA decreased in certain sectors, sales value per unit area improved. Socially, the sector generated significant employment and wage multipliers; however, challenges remain with an ageing workforce, low recruitment rates, and limited female participation. A high level of innovation was observed, including advancements in process control and organizational structures.

**Discussion**
This inaugural sustainability report provides vital, transparent data that strengthens Ireland's ability to meet EU sustainability targets and national aquaculture goals. It aligns with the EU's strategic objectives to foster competitive and resilient aquaculture, while supporting Ireland's commitment to building a climate-neutral and socially inclusive seafood sector. The report establishes a critical foundation for evidence-based policymaking, strategic planning, and continuous sectoral improvement. The report also provides data which can be used in the curation and further development of the social license for these aquaculture activities in coastal and rural communities.

**Conclusion**
The findings affirm that the Irish aquaculture sector is well-positioned to contribute to EU and national sustainability ambitions. Ongoing monitoring, innovation, and adaptive management are essential to maintaining progress and securing a sustainable future for aquaculture in Ireland and beyond.

# SUPPORTING SUSTAINABLE AQUACULTURE THROUGH INDEPENDENT SCIENTIFIC ADVICE

Anne M. Cooper*[1], Ena Briesemeister[1], and Ann-Lisbeth Agnalt[2]

[1] International Council for the Exploration of the Sea (ICES), H. C. Andersens Boulevard 44-46, 1553 Copenhagen V, Denmark
[2] Institute of Marine Research, Austevoll Research Station, Sauganeset 16, Storebø 5392, Norway

Email: Anne.Cooper@ices.dk

In the North Atlantic, wild capture fisheries are longstanding and deeply rooted activities, governed by well-established regulatory frameworks. These are shaped by global agreements and implemented through relatively cohesive, quantitative management systems across the region. The sector benefits from clear governance structures, coordinated data streams, robust scientific cooperation, and well-organized stakeholder networks—factors that together underpin a mature and effective science-policy interface essential for sustainable fisheries management.

In contrast, aquaculture in the region, while growing in importance, is characterized by more fragmented governance. As a national competency, approaches to aquaculture development and regulation vary widely, and the systematic exchange of best practices is limited. The EU has taken important steps to support the sustainable growth of the sector, notably through the *Strategic Guidelines for a more sustainable and competitive EU aquaculture*[1]. These guidelines urge Member States to define and monitor environmental performance using appropriate indicators, while promoting the alignment of aquaculture with EU environmental, social, and economic objectives.

However, key questions remain: What constitutes a "best practice"? How much monitoring is sufficient? What do the data mean? And who determines what qualifies as "good" environmental performance?

As the demand for responsibly produced aquatic foods continues to rise, aquaculture must meet complex and often competing sustainability goals. Addressing these challenges requires more than localized decision-making—it demands coordinated, science-based approaches grounded in transparency, accountability, and collective learning.

The International Council for the Exploration of the Sea (ICES) has a long-standing role in providing independent, consensus-based scientific advice to national governments, regional fisheries bodies, and the European Union—primarily in the context of wild capture fisheries. Today, ICES is also advancing work on aquaculture as part of its broader commitment to the Ecosystem Approach. This includes enhancing understanding of marine ecosystems and the services they provide and using this knowledge to develop advice that supports conservation, management, and sustainability across sectors.

This presentation will showcase two successful case studies where independent scientific advice contributed to management outcomes in the Northeast Atlantic—one in commercial fisheries and one in Atlantic salmon aquaculture. It will conclude with a discussion on how similar science-policy collaboration could support sustainable marine aquaculture in EU Member States, particularly through the identification and application of relevant environmental, social, and economic indicators through the sharing of best practices and independent scientific advice. Such efforts can improve the tractability, transparency, and effectiveness of aquaculture governance and help translate policy ambitions into measurable outcomes.

# A NEW STRATEGY TO PREVENT EMERGING *Lactococcus garvieae* INFECTIONS BY USING AURAAQUA, A MIXTURE OF NATURAL PLANT EXTRACTS AND ORGANIC ACIDS, IN VITRO AND EX VIVO

N. Corcionivoschi, I. Balta, F. Simiz, D. Stef, I. Pet, G. Dumitrescu, T. Iancu, I. Cretescu and L. Stef

Bacteriology Branch
Veterinary Sciences Division
Agri-Food and Biosciences Institute
Northern Ireland, Belfast BT4 3SD, UK
E-mail: Nicolae.corcionivoschi@afbini.gov.uk

## Introduction

*Lactococcus garvieae* (*L. garvieae*), a Gram-positive lactic acid bacterium belonging to the Streptococcaceae family, has gained notoriety as a significant pathogen in aquaculture, particularly in freshwater and marine fish, including high-value species like rainbow trout and European Sea Bass —causing piscine lactococcosis. The disease is marked by high morbidity, haemorrhagic symptoms, and systemic infections. Its adaptability and capacity for biofilm formation complicate eradication and contribute to persistent outbreaks. Conventional antibiotic treatments are losing effectiveness due to rising antimicrobial resistance, necessitating the exploration of safer, more sustainable alternatives. Plant extracts and organic acids (OAs) have emerged as promising candidates due to their natural antimicrobial, anti-inflammatory, and immunomodulatory effects. This study evaluates the efficacy of a plant extract and organic acid mixture AuraAqua (Aq), against *L. garvieae* in vitro (CHSE-214 fish epithelial cell line) and ex vivo (fish red blood cells), focusing on its impact on bacterial growth, virulence gene expression, host immune responses, and cytotoxicity.

## Materials and Methods

This study employed CHSE-214 epithelial cells and rainbow trout red blood cells to model infection. The MIC and MBC of Aq were determined using standard dilution techniques. The anti-virulence activity of Aq at the established MIC (0.125%) was assessed by, measuring bacterial growth, EPS gene expression, biofilm formation, cytotoxicity via LDH release, adhesion of *L. garvieae* to epithelial cells and gene expression of haemolysins (hly1, hly2, hly3). Immunomodulatory and inti-inflammatory effect of Aq was assessed by measuring host inflammatory cytokine responses (IL-1β and IL-8). Finally, the protective effect of Aq was measured by challenging trout red blood cells with *L. garvieae* and measuring haemolysis in an ex vivo assay. Gene expression was analysed using quantitative RT-PCR, and statistical analysis was performed using t-tests and ANOVA.

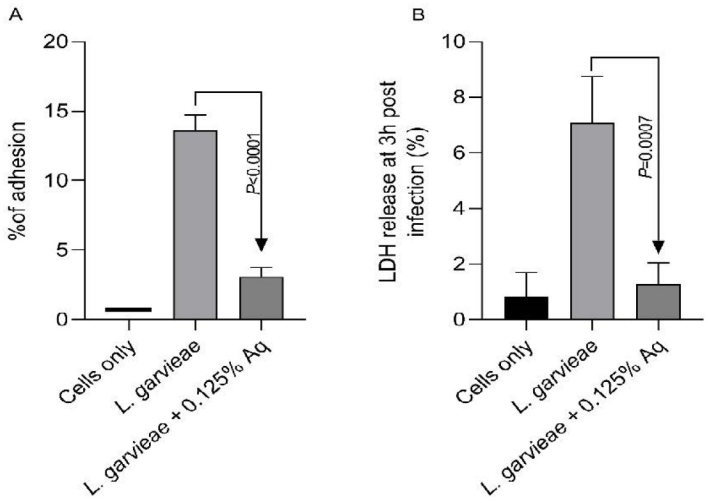

Fig. 1. The impact of Aq on the adhesion of L. garvieae to CHSE-214 cells (A) and on bacteria induced cytotoxicity (B). The p value indicates a very significant difference when 0.125% Aq was added to the infection assay ($p < 0.0001$).

*(Continued on next page)*

**Results**

Aq showed inhibitory and bactericidal activity at 0.125% (MIC) and 0.75% (MBC), respectively.

At a concentration of 0.125% Aq significantly reduced number of *L. garvieae* vilulence factors including growth, EPS gene expression (epsA, epsB, epsC, etc.), and biofilm formation. In addition, Aq inhibited bacterial adhesion to CHSE-214 cells and reduced cytotoxic effects (Fig. 1).

In ex vivo experiments a significant reduction in haemolysis was observed when Aq was co-administered with *L. garvieae* in red blood cell assays ($p = 0.02$). Expression of *L. garviae* virulence genes hly1 and hly3 was significantly downregulated, while hly2 showed no significant change. IL-1β and IL-8 expression was significantly reduced in infected CHSE-214 cells treated with Aq, highlighting its anti-inflammatory potential.

These effects collectively indicate Aq's ability to suppress bacterial virulence and mitigate host inflammatory responses without harming host cells.

**Conclusion**

This study demonstrates that a natural blend of plant extracts and organic acids (Aq) can significantly reduce the pathogenic potential of *L. garvieae* by inhibiting key virulence factors such as exopolysaccharide production, haemolysin gene expression, and host cell adhesion. Additionally, Aq reduces inflammation and cytotoxicity in host cells, suggesting its dual benefit as both an antimicrobial and immunomodulator. These findings position Aq as viable non-antibiotic alternatives for controlling *L. garvieae* infections in aquaculture, contributing to sustainable fish health management strategies and addressing the growing need for antibiotic-free disease control.

# THE EFFECTS OF CRYOPRESERVED SPERM USE ON OFFSPRING TOLERANCE TO ENVIRONMENTAL STRESSORS IN SALMON RESTOCKING PROGRAM

Valérie Cornet*, Alexandre Erraud, Manon Poignet, Jérôme Lambert, Patrick Kestemont

Research Unit in Environmental and Evolutionary Biology (URBE)

## Introduction

The Atlantic salmon is an emblematic species of Western Europe rivers that flow into the North Atlantic Ocean, yet its populations have been in decline throughout the 20th century. Several European programs in Western Europe (*ie*, such as those in Denmark, Germany, Wales or Belgium), aim to sustainably restore salmon habitats and populations by implementing restocking actions-including the release of emerging yolk fry and parr, removal of migration barriers, and habitat restoration measures. Nevertheless, adult salmon returns remain relatively low and show considerable interannual variability. The use of cryopreserved sperm from genetically valuable males in aquaculture production provides a promising tool for conservation. It allows for long-term storage of genetic material and helps maintaining genetic diversity (Magnotti et al. 2018). This may, for example, help compensate for the lack of returning anadromous male in certain years. Preliminary experiment using cryopreserved semen resulted in hatching of 60% of fertilized eggs suggesting that such cryopreserved sperm could be used for annual breeding programs when the stock of anadromous males is too low. However, cryopreservation is also known to cause cell damage, affecting the plasma membrane, mitochondrial membrane potential, and sperm motility, ultimately impacting reproductive success (Erraud et al. 2024). Although no significant effects of cryopreservation was observed on fertilization rates, growth, survival nor pathogen resistance during the embryo stage, Nusbaumer et al. (2019) found that fertilization by cryopreserved sperm significantly reduced larval growth after hatching.

In addition, salmon released through restocking programs will be increasingly exposed to the impacts of climate change. It is now well established that rivers are experiencing accelerated warming during the summer months, along with a higher frequency of extreme temperature events. These changes are particularly concerning for cold-water species such as Atlantic salmon, which are highly sensitive to elevated water temperatures (Buisson et al., 2008).

Our experiment aimed at evaluating the effect of using cryopreserved sperm from the Meuse River strain (Belgian) on fry development and their resistance to environmental stressors such as river warming and bacterial infection. The effects of two stressors experienced by hatchery-reared juveniles upon release were tested: daily thermal fluctuations specific on the recipient river and an infection with a bacterial pathogen. The environmentally realistic thermal conditions tested in this study were set based on temperature records from three Belgian rivers (Ry de Ferron (constant 10°C), Berwinne (6.5–12.3°C), and Ry d'Oxhe (4.5–16°C) rivers).

## Material and Methods

Artificial reproductions were performed using anadromous male breeders (using both fresh and cryopreserved sperm) and 2+ female breeders. Eggs were collected, pooled and divided into batches of 300 eggs. They were then fertilized with fresh and cryopreserved sperm to obtain a standard sperm-to-egg ratio of 10°C and transferred into individual vertical micro-incubators supplied with recirculated freshwater at 9.0 ± 0.4°C throughout the incubation period. Fifteen days post-hatching, salmon fry (N = 360) from fertilization with fresh and cryopreserved sperm were subjected to thermal stress as such: a constant temperature of 9 °C, a daily fluctuation between 7-12°C, or a fluctuation between 3-15°C. Biometric variables such as size, weight, and yolk sac size were measured at the start of the experiment, after 24 h and 11 days of thermal stress exposure. Nine individuals per condition were euthanized using a final concentration of 200 mg $L^{-1}$ buffered MS-222 to collect biological material for molecular analyses via qPCR.

*(Continued on next page)*

Following thermal stress, half of the remaining organisms were exposed through a bath infection to the bacterial pathogen *Aeromonas salmonicida achromogenes* at $1.41 \times 10^9$ CFU/mL for 6 hours at 9°C; the other half was kept as a control group uninfected. After 6 h of bacterial challenge, half of the exposed fry and half of the control fry were euthanized and sampled for molecular analyses using qPCR analyses.

**Results and discussion**

This study represents the first investigation assessing the impact of sperm cryopreservation on the development of yolk-sac fry intended for restocking, as well as their resistance to two successive environmental stressors: thermal stress and bacterial challenge. Particularly, the higher daily thermal fluctuations (3–15°C) resulted in reduced growth rates and yolk reserves. These phenotypic observations were sustained by transcriptomic analyses, which revealed that progeny derived from cryopreserved sperm exhibited upregulated expression of genes associated with antioxidant defences and energy metabolism. These high fluctuated temperatures also induced an increase in intracellular reactive oxygen species (ROS), leading to heightened energy expenditure to counteract oxidative stress. Consequently, energy allocated to stress responses was unavailable for somatic growth. It is therefore likely that fry originating from cryopreserved sperm possess lower critical thermal minima and maxima compared to those produced with fresh sperm.

Moreover, the bacterial challenge demonstrated that fry from the cryopreserved group were able to face the bacterial infection with an effective immune response only when they had not been previously exposed to thermal stress (i.e., 3-15°C). Our results suggest that sperm cryopreservation could have reduced the capacity of progeny to cope with multiple environmental stressors. While the use of cryopreserved sperm remains a viable strategy for restocking salmon populations, caution is warranted when releasing these individuals into rivers subject to substantial daily temperature fluctuations, such as the Ry d'Oxhe in Belgium.

# NUTRIENT-DRIVEN GROWTH RESPONSES OF HAWAIʻI NATIVE LIMU MANAUEA LOLOA *(Gracilaria parvispora)* AND INVASIVE *Gracilaria salicornia*: CENTERING NATIVE HAWAIIAN AQUACULTURE RESTORATION THROUGH PURPOSE, PLACE, AND PARTNERSHIP

Seaenna Correa-Garcia

University of Hawaiʻi - Hawaiʻi Institute of Marine Biology
46-007 Lilipuna Rd
Kaneohe, HI 96744
Email: seaenna@hawaii.edu

Limu (native macroalgae) plays a critical role in Hawaiʻi's nearshore ecosystems, acting as a natural biofilter, providing habitat and sustenance for marine life, and serving as a valuable resource for human consumption while holding deep cultural significance. However, the decline of native limu species due to environmental threats and human impacts has underscored the need for ongoing restoration efforts. Furthermore, little is documented about the specific conditions native limu require to thrive in cultivation systems that support broader restoration efforts. This study aims to determine the optimal growth conditions for Limu Manauea Loloa (*Gracilaria parvispora*) to support restoration and sustainable aquaculture.

In addition, the study includes a Hawaiʻi invasive species, *Gracilaria salicornia,* to compare growth responses across a nutrient availability gradient, helping to understand competitive dynamics and environmental thresholds influencing both species. The study evaluates key environmental factors influencing limu growth by replicating salinity and nutrient levels found at sites with varying cultivation success, such as loko iʻa and restorative aquaculture facilities. It assesses how these conditions affect biomass production and photosynthetic efficiency in Limu Manauea Loloa and *G. salicornia*. Findings will inform restoration strategies aligned with ecological and cultural priorities, fostering sustainable limu stewardship.

Loko iʻa, traditional Hawaiian fishponds, represent a foundational form of Indigenous aquaculture and coastal resource management. Once abundant across the islands, many loko iʻa have deteriorated due to neglect, development, and invasive species. Restoring these systems not only revitalizes traditional food production and strengthens biocultural connections but also creates ideal habitats for native limu to flourish. By understanding the conditions that support limu growth in loko iʻa, this research supports ongoing fishpond restoration efforts and highlights the interconnectedness of limu health and ecosystem stewardship.

This research is a collaborative effort rooted in community-based resource management, guided by the knowledge of local practitioners and organizations. By bridging cross-disciplinary efforts, we aim to develop practical recommendations that empower community-led restoration. Through purpose, place, and partnerships, this study contributes to revitalizing Hawaiʻi's native marine resources.

Data collection is expected to conclude in early summer 2025, with results to follow shortly thereafter.

# PITUITARY mRNA EXPRESSION IN GREATER AMBERJACK *Seriola dumerili* EXHIBITING IMPAIRED SPERMATOGENESIS

## Introduction

The greater amberjack *Seriola dumerili* is a promising aquaculture candidate for the Mediterranean Sea. However, hatchery-produced individuals exhibited severe reproductive dysfunctions, characterized by (a) incomplete gametogenesis and (b) the absence of spontaneous spawning, when reared in tanks or sea cages, respectively (Lancerotto et al., 2025). We present here a comparative analysis of the pituitary transcriptome of wild and hatchery-produced greater amberjack males sampled during the active gametogenesis, as part of a research program aimed at describing the effects of rearing in captivity on gene expression along the reproductive axis of this species.

## Material and Methods

Pituitaries from wild and hatchery-produced males were sampled in 2022 on board a fishing vessel and in a fish farm in Salamina (Greece), respectively, and preserved in RNA later®. To assess the reproductive state, testis samples were fixed in Bouin's solution, embedded in paraffin wax, sectioned and stained with haematoxylin-eosin. Fish were then assigned to one of the following groups: WILD (wild fish undergoing active spermatogenesis; N = 4); NormalF (farmed fish undergoing active spermatogenesis; N = 4); DysF (farmed fish with arrested, dysfunctional, spermatogenesis; N = 2). Pituitary total RNA extraction was performed by RNeasy® Plus Mini kit (Qiagen, Germany), mRNA libraries were prepared by SureSelect Strand Specific RNA Library Preparation kit (Agilent Technologies, California, U.S.) and paired-end sequencing was performed on the Illumina NextSeq platform (Illumina Inc., California, U.S.). Differential gene expression analysis was carried out using DESeq2. DAVID (https://david.ncifcrf.gov/tools.jsp) was used to perform the functional annotation of Differently Expressed Genes (DEGs) and the Gene Ontology enrichment analysis. A protein-protein interaction (PPi) network based on DEGs associated with each comparison was built using STRING (https://string-db.org). DEGs were mapped to KEGG pathways using KEGG Mapper – Search (https://www.genome.jp/kegg/mapper/search.html).

## Results and Discussion

The transcriptome analysis identified 18176 genes, of which 16234 were common to the three groups, and 889, 90, and 8 genes were specifically expressed in WILD, NormalF and DysF, respectively (Fig. 1). Differentially expressed gene (DEG) analysis revealed 301 and 376 DEGs in DysF vs. WILD and NormalF vs. WILD comparisons, respectively, while no DEGs were detected between DysF and NormalF groups (Table 1). Pathway enrichment analysis highlighted significant alterations in *purine* and *nucleotide metabolism* pathways in DysF vs. WILD, and in *antiviral defense* biological process in NormalF vs. WILD. PPi analysis identified broad regulatory networks involving 246 proteins across eleven functional categories in DysF vs. WILD, and 382 proteins across ten categories in NormalF vs. WILD. KEGG analysis showed DEGs enriched in 62 (DysF vs. WILD) and 84 (NormalF vs. WILD) pathways. Notably, several dysregulated pathways were common to both farmed fish groups and were associated with reproductive functions, including GnRH and ErbB signaling pathways. Among DEGs, genes encoding for Neuron-derived neurotrophic factor, Proenkephalin, Gamma-aminobutyric acid, Insulin-like Growth Factor 1, Beta-arrestin, Muscarinic acetylcholine and Cholinergic receptors were found.

*(Continued on next page)*

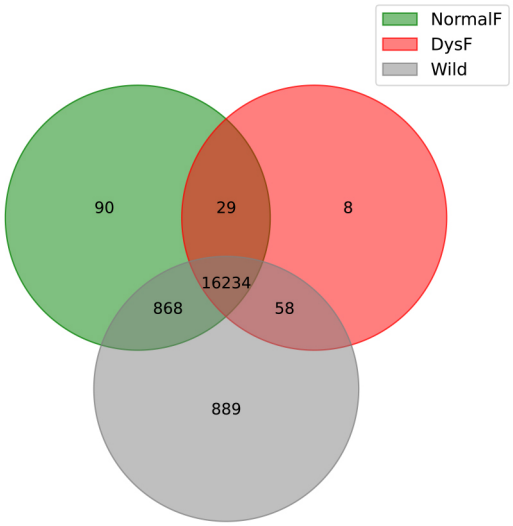

**Fig. 1.** VENN diagram of shared and unique expressed genes of wild (WILD), dysfunctional farmed (DysF) and non-dysfunctional farmed (NormalF) fish.

**Table 1.** Number of upregulated and downregulated genes in the three groups of greater amberjack males.

| | TOTAL GENES | DEGs | UP | DOWN |
|---|---|---|---|---|
| **DysF vs. WILD** | 18,086 | 301 | 141 | 160 |
| **NormalF vs. WILD** | 18,168 | 376 | 163 | 213 |
| **DysF vs. NormalF** | 17,287 | - | - | - |

The data reveal widespread disruption of gene expression and associated pathways in hatchery-produced male greater amberjack. This disturbance influences a variety of biological processes and suggests that the spermatogenic impairment reported by Lavecchia et al. (2023) may stem from broad suppression of pituitary function, possibly driven by dysregulation within the opioid, endocannabinoid, and dopaminergic systems.

# POTENTIAL IMPACT OF CLIMATE CHANGE ON THE SPREAD OF NERVOUS NECROSIS VIRUS: A CRITICAL THREAT TO MARINE ECOSYSTEMS AND GLOBAL FOOD SECURITY

Marianna Costa[1,2]*, Rosamaria Pennisi[1], Fabiano Capparucci[1], Sabrina Natale[1], Maria Teresa Sciortino[1]

## Introduction

Viral Nervous Necrosis Virus (NNV), a member of the Nodaviridae family, is recognized as one of the most devastating viral pathogens in marine aquaculture worldwide. Its impact is especially severe in high-value species such as groupers (*Epinephelus spp*.), where it predominantly targets the central nervous system, causing vacuolation of brain and retinal tissues. This results in erratic swimming behavior, high mortality rates in larvae and juveniles, and considerable economic losses.

In parallel, the intensification of climate change has introduced new, pressing variables influencing host-pathogen-environment interactions, drastically altering marine ecosystems. In particular, the rise in sea surface temperatures, a direct consequence of climate change, is destabilizing marine environments and exacerbating disease outbreaks. These elevated temperatures are compromising fish immune defenses, making them more vulnerable to infections like NNV. The interplay between changing climate conditions and pathogen dynamics underscores the urgency of developing robust surveillance strategies for early detection and management of NNV. In this study, we assessed the effect of temperature on viral replication to better understand how climate-related stressors, particularly warming oceans, may amplify disease dynamics and impact aquaculture. Furthermore, we investigated the presence and viability of NNV in wild Mediterranean grouper specimens, shedding light on how the virus's geographic distribution and pathogenic potential are shifting in response to changing environmental conditions driven by climate change.

## Materials and Methods

To evaluate the impact of rising temperatures, viral replication was assessed at 25°C and 28°C using two different multiplicities of infection (MOI 1 and MOI 10). Cytopathic effects were monitored daily under an inverted microscope, and viral titers were evaluated. In addition, brain tissues collected from wild grouper specimens were processed for molecular and virological analyses. Total RNA was extracted, reverse-transcribed, and analyzed via real-time PCR targeting the RNA1 segment of NNV. For viral isolation, tissue homogenates were inoculated onto SSN-1 cell lines.

## Results

In vitro infection of SSN-1 cells resulted in marked cytopathic effects, such as cell rounding, vacuolation, and detachment, by day six post-infection, confirming successful viral replication and isolation. Temperature-based assay revealed that viral replication was significantly higher at 25°C than at 28°C across both MOI conditions. This suggests that elevated temperatures, although generally considered favorable for pathogen proliferation, may instead compromise the host's physiological state, rendering fish more susceptible to infection even if viral replication itself is reduced. In addition, molecular screening confirmed the presence of NNV RNA in grouper specimens. These findings emphasize the relevance of temperature as a modulating factor in host-pathogen interactions and support the need for adaptive management strategies in the face of global climate change.

# IDENTIFICATION OF REPRODUCTIVE CYCLE BIOMARKERS IN CARPET SHELL CLAM (*Ruditapes decussatus*) AND MEDITERRANEAN MUSSEL (*Mytilus galloprovincialis)*

María M. Costa *[1], Sonia Dios[1], Camino Gestal[1], Gabriel Pérez-Tierra[1], Elsa Vázquez[2], Miguel A. Lastres[3], Félix Álvarez[1].

**Introduction**

The reproductive cycle of bivalve molluscs plays a critical role in their physiology, population dynamics, and commercial value. In species such as the Mediterranean mussel (*Mytilus galloprovincialis*) and the carpet shell clam (*Ruditapes decussatus*), understanding the timing and progression of gonadal development is essential for optimizing broodstock management, improving hatchery efficiency, and supporting sustainable aquaculture practices[1,2]. Traditionally, the identification of reproductive stages relies on histological analysis of gonadal tissue, which, although informative, is labor-intensive, requires specialized expertise, and is not suited for high-throughput applications[3]. In this context, the development of molecular tools capable of accurately identifying reproductive stages rapidly and cost-effectively has become increasingly relevant. Molecular markers offer the potential for automation, reproducibility, and early-stage detection[4]. This study aims to identify reproductive stage-specific molecular markers in *M. galloprovincialis* and *R. decussatus*, and assess their potential for improving reproductive monitoring and sustainability in bivalve aquaculture.

**Material and methods**

To obtain individuals representing three key reproductive stages (juvenile, pre-spawning, and post-spawning), spawning was induced in adult specimens of *M. galloprovincialis* and *R. decussatus* under controlled laboratory conditions. Juvenile samples were obtained from the resulting progeny. Adults that released gametes during induction were preliminarily classified as post-spawning. At the same time, those from the same batch that did not spawn were initially assumed to be in the pre-spawning stage. This stage assignment was subsequently verified through classical histological analysis of gonadal tissue using hematoxylin-eosin staining. Representative individuals from each confirmed stage were selected for downstream molecular analyses. In the first phase of the study, we investigated the expression profiles of a set of candidate genes previously described in the literature (*vitellogenin, foxl2, vasa*-like gene*, piwi,* or *bmp2a*) as being involved in bivalve gametogenesis and gonadal maturation. Gene expression was quantified using quantitative PCR (qPCR), and results were analyzed to assess correlations with histologically defined stages. Since candidate gene expression did not provide sufficient resolution to distinguish between stages, a second phase employing an omics-based approach was implemented. This included the high-throughput identification of proteins and metabolites differentially expressed across the reproductive stages. Proteomic and metabolomic analyses were performed using mass spectrometry techniques, allowing for a broader and more unbiased search for potential biomarkers.

**Results and Discussion**

In the Mediterranean mussel, the expression levels of *vitellogenin* and *piwi* genes varied across the three analyzed stages. *Vitellogenin* expression was elevated in the post-spawning stage compared to the juvenile and pre-spawning stages (Fig. 1A). However, for *piwi* expression, the highest expression levels were found in the pre-spawning stage (Fig. 1B), although high individual variability was observed. Regarding metabolite concentrations in gonadal tissue, glucose levels showed clear differences among the developmental stages, with a marked increase in the pre-spawning stages. In contrast, lactate and cholesterol concentrations appeared unaffected by developmental stage, remaining at consistently low levels across all three groups (Fig. 2). In *R. decussatus*, gene expression patterns were more variable. *Vitellogenin* did not show a consistent trend across the different gonadal stages, and both males and females displayed high individual variability in expression levels (Fig. 3A). In contrast, *piwi* expression in males appeared to be more concentrated in histology-defined stages 2 and 3 (Fig. 3B), although no clear pattern was observed in females. Overall, *R. decussatus* exhibited high inter-individual variation in gene expression, with no consistent association between expression levels and gonadal stage for either marker. Although proteomic and metabolomic analyses have been initiated, the results are still under evaluation and are therefore not included in the present report. It is expected that this integrative approach will provide further insight and help clarify the patterns observed in the gene expression and metabolite data presented here.

*(Continued on next page)*

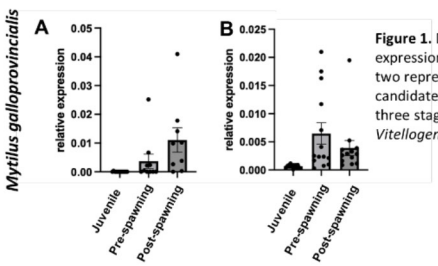

**Figure 1.** Differential gene expression in gonads of two representative candidate genes in the three stages analyzed. (A) *Vitellogenin* and (B) *piwi*.

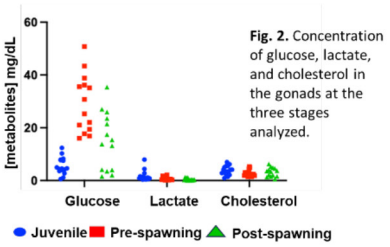

**Fig. 2.** Concentration of glucose, lactate, and cholesterol in the gonads at the three stages analyzed.

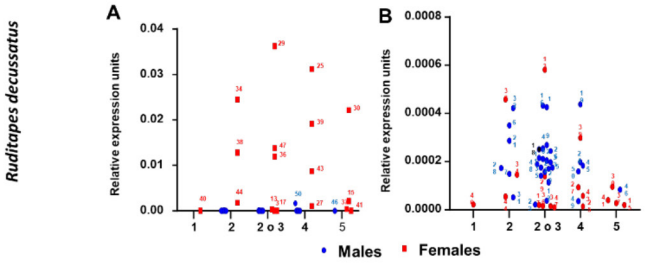

**Fig. 3**. Differential expression by sex in gonads of two representative candidates genes in the five stages previously determined by histology. (A) *Vitellogenin* and (B) *piwi*.

## Conclusions

This study reveals that transcript-level markers are unreliable for staging reproduction in bivalves due to high individual variability, especially in *R. decussatus*. However, metabolic profiling in *M. galloprovincialis* showed consistent glucose patterns linked to aerobic metabolism. These findings support proteomic and metabolomic approaches as more robust alternatives for identifying reproductive biomarkers, especially in species with variable reproductive cycles.

# EFFECT OF THE TEMPERATURE ON THE SURVIVAL AND FEED INTAKE OF BANDED CARPET SHELL CLAM, *Polititapes rhomboides*

María M. Costa *[1], Sonia Dios[1], Lourdes Nieto[1], Camino Gestal[1], Berta Barreiro[2]. Tania Ballesteros[3]

## Introduction

The production of banded carpet shell clam, *Polititapes rhomboides*, has drastically declined in recent years in Galician markets, posing a serious threat to the sustainability of local shellfisheries[1]. Episodes of mass mortality have been linked to an increased prevalence of bacterial infections, with environmental conditions suggested as a contributing factor[2]. Among these, seawater temperature has emerged as a key driver. Analyses of mortality events revealed that they were often preceded by periods of above-average temperatures[3], supporting the hypothesis that thermal stress, alone or in combination with other environmental factors, may compromise the immune capacity of *P. rhomboides*[4]. Given that this species is not currently cultured and lacks a controlled seed supply, understanding its response to rising temperatures is essential for preserving the natural stocks. This study examines temperature as a key environmental factor affecting its survival and aims to support adaptive management under climate change.

## Material and methods

Specimens of *P. rhomboides* were collected from three natural shellfish beds located in the Ría de Vigo (NW Spain) (Fig.1) using a traditional artisanal harvesting technique ("*marisqueo a flote"*), which involves manually deploying a rake-like dredge ("*raño"*) from a small boat to extract clams from shallow subtidal sediments. Approximately 150 individuals were collected from each site. Upon arrival at the aquarium, the clams were held for seven days in an open-flow seawater system supplied with 100 µm-filtered seawater, allowing them to feed on naturally occurring microalgae. This acclimation period ensured stabilization before experimental manipulation. Following acclimation, clams from each site were randomly distributed among the three seawater temperature treatments: 15°C (control), 18°C, and 21°C. The experiment was conducted in three 400 L closed-circuit tanks, each maintained at one of the target temperatures. Within each tank, twelve mesh baskets were used to separate replicate groups: four replicates of ten individuals from each of the three collection sites. This setup allowed for the simultaneous exposure of all replicates to their respective temperature treatment under identical conditions. For the 18°C and 21°C treatments, seawater temperature was gradually raised over 2–3 days (~1.5°C/day) to minimize thermal stress during acclimation. Throughout the 30-day experiment, clams received a total of 5 L of a mixed microalgae suspension (T-Iso and *Rhodomonas lens*) daily. Mortality was daily recorded before the addition of the microalgae. Food intake was assessed once per week by measuring the average reduction in phytoplankton concentration in each tank, calculated as the difference between the initial and remaining algal levels after consumption.

## Results and Discussion

Across all three collection sites, clams exhibited higher mortality rates at the highest temperature treatment (21°C) (Fig. 2). Clams from the Cíes shellfish bed showed the greatest sensitivity, with mortality rates approaching 25% by the end of the experiment. In contrast, individuals from Cabo do Mar displayed intermediate mortality levels, reaching approximately 12%, while those from Tirán exhibited the lowest mortality, remaining below 5%. These results suggest that the clams' geographic origin may influence their thermal tolerance, potentially reflecting site-specific adaptation to local environmental conditions. The decrease in phytoplankton consumption by clams from week 2 to week 5 became more pronounced with increasing temperature. At 15 °C, consumption declined by only 7.49%, whereas at 18 °C the reduction reached 8.62%. The greatest decrease was observed at 21 °C, with a drop of 11.08% (Fig. 3). This trend suggests that elevated temperatures may lead to behavioral responses such as shell closure, a common protective strategy in bivalves under thermal stress. By reducing valve opening time, clams likely limit their feeding activity, which could explain the progressive decline in phytoplankton intake observed at higher temperatures.

*(Continued on next page)*

**Figure 1.** Location of the three shellfish beds: Cíes, Cabo do Mar, and Tirán. The figure shows a general map of Spain, followed by a detailed view of Galicia and, finally, the Ría de Vigo, where the shellfish beds are marked.

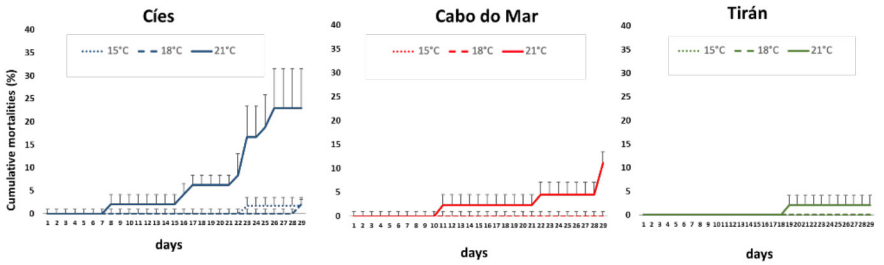

**Figure 2.** Cumulative mortality (%) of *Polititapes rhomboides* over a 30-day period under three seawater temperature treatments (15°C, 18°C, and 21°C). Data are shown separately for each collection site (Cíes, Cabo do Mar, and Tirán). Error bars represent standard error of four replicates per treatment.

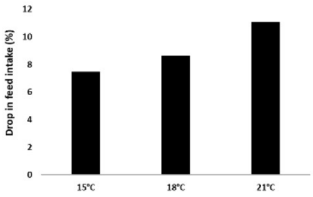

**Figure 3.** Relative change in feeding activity of *Polititapes rhomboides* between the first and last week of the experiment, calculated as the ratio of average t60/t0 values (phytoplankton concentration at 60 minutes relative to time 0) for each week, under three temperature treatments (15°C, 18°C, and 21°C). Higher values indicate a greater reduction in feeding activity over time. No error bars are shown, as the ratio represents a comparison between independent weekly averages rather than paired replicates.

## Conclusions

This study highlights that elevated seawater temperatures significantly affect the survival and feeding of *P. rhomboides*. Mortality differences among shellfish beds suggest local adaptation, while reduced phytoplankton intake under heat stress points to behavioral changes that may limit food consumption. These findings underscore the vulnerability of natural stocks to climate-induced warming and the need for site-specific management strategies to ensure their sustainability. While temperature was examined in isolation, future analyses within the framework of the RIFA project (REDEMAR. Xunta de Galicia) will consider additional environmental factors to better understand the multifactorial drivers of stress in natural populations.

# AN INTEGRATED, LOW-COST COMMUNITY-BASED MODEL OF RESTORATIVE COASTAL AQUACULTURE WITH NUTRIENT DIVERSION AS A NATURE-BASED SOLUTION

Barry António Costa-Pierce*, Ronald Zweig, Earle Barnhart, and Hilda Maingay

Ecological Aquaculture International, LLC
Nord University, Bodø, Norway
and
The Green Center, Inc.
Biddeford ME East Falmouth, MA, USA
E-mail: bcp@oceanfoods.org

The global climate crisis caused by unsustainable hydrocarbon emissions has placed Humanity and our Earth into a new, sorrowful era of biosystems collapses and community catastrophes. The global scientific consensus used to urge nation states to make significant, credible emission reductions has not been enough, as wars, political malfeasance and malaise by arrogant, corrupt leaders are in ascendance. What can an individual scientist, a family, a community do if nation states are so irresponsible for everything we hold dear? Of course, we can decrease emissions and overconsumption as much as possible by moving to renewable energy, better diets, and become climate activists. These are global priorities for every citizen and family. Our community of aquatic scientists has additional scientific responsibilities to understand as much as possible and propose innovative actions to assist in the recovery of aquatic ecosystems from accelerated anthropogenic damage. Actions go beyond a need to understand IPCC projections of climate impacts from carbon emissions.

Ocean acidification is a terrifying concept; but the most urgent priority is coastal/freshwater ecosystem acidification from nutrients, especially nitrogen (N), which has been called "the forgotten element of climate change". Wastewater discharges to aquatic ecosystems from coastal urbanization and unsustainable agriculture control the Earth's coastal and freshwater N, P cycles. The Millennium Ecosystem Assessment predicted an increase in global sewage emissions of 12.0–15.5 Tg N and 2.4–3.1 TgP/year by 2050, and these may have already been exceeded. Lu et al. (2024) found that as a city grows energy use becomes more efficient and greenhouse gas emissions (GHG) decrease, but that water use increases exponentially; thus, wastewater discharges grow at a faster rate than a growing urban population. Tuholske et al. (2021) showed that 58% of coral reefs and 88% of seagrass beds of the 135,000 watersheds mapped globally were exposed to wastewater N inputs.

GHG emissions from unsustainable burning must decrease; but we are in a major nearshore, coastal/freshwater acidification crisis due to the accelerating quantities of nutrients (N to estuarine/coastal ecosystems, P to freshwaters) being discharged causing severe hyper-eutrophication and a cascade of adverse impacts to ecosystem functions and critical habitats. Coastal/freshwater acidification is due to the intensity of nutrient loading rates as there are clear links between acidification, hypoxia, intense algal blooms, and eutrophication. $pCO_2$ conditions being experienced now in coastal/freshwater ecosystems are not expected to occur in the open ocean within the next hundred years, if ever, given IPCC projections of anthropogenic $CO_2$ increases.

Nutrient discharges are the main cause of coastal/freshwater acidification, not GHG $CO_2$ dissolving into water. Many (most?) freshwater and coastal ecosystems are net heterotrophic (Duarte and Prairie 2005); they are "sewage-fuelled" marine ecosystems discharging $CO_2$ to the atmosphere. Jamaica Bay off New York City is a hypereutrophic estuary that receives ~90% of its N from four wastewater treatment plants that discharge ~ 1 billion liters of effluent daily. pCO2 concentrations in bottom waters in summer exceed 2000 μatm (the atmosphere is ~437 ppm now) (Wallace et al. 2014). Almost 30 years ago, Frankignoulle et al. (1998) found an area of European estuaries emitted ~3000 MT $CO_2$/d to the atmosphere; $CO_2$ emissions from the Scheldt estuary, Belgium/Netherlands were 2/3 due to heterotrophy and 1/3 due to ventilation. Bastviken et al. (2024) found that, given recent global freshwater $CO_2$ emissions of ~1.4 PgC ($CO_2$ eq)/year, freshwaters were a very important component of the global GHG balance comprising ~79% of the terrestrial GHG sink. They stated that, "the terrestrial GHG sink may be smaller than currently believed, and data on GHG release from inland waters are needed in future revision of net continental GHG fluxes."

*(Continued on next page)*

"Solutions" to accelerating urban wastewater discharges to coastal/freshwater systems are dominated by proposals by policy-makers, regulators, sanitary engineers and scientists for the massive expansion of capital-intensive sewer systems, the requiring installations of "alternative septic systems, or dilution "offshore" in the hope of restoring the water quality of valuable aquatic ecosystems. Such calls require large and unprecedented government expenditures and residential tax increases.

An alternative community-based, integrated restorative aquaculture with UD nutrient diversion model is underway in a coastal area of New England, US. It illustrates the potential of nature-based, solutions which can accelerate the development of low trophic level aquaculture and help ameliorate the nutrient/carbon crisis of aquatic ecosystems. Efforts combined applied science from Europe and North America in shellfish aquaculture with urine diversion (UD). UD is the concept of separating and collecting urine from wastewater at the source for reuse as fertilizers (struvite). Approximately 80% of the N and ~60% of P in wastewaters are from urine; but urine is only ~1% of wastewater volume (Wald 2022). The Green Center developed low-cost UD and the community approved zoning and guidelines for shellfish aquaculture as public-private partnerships. The community provided shellfish farmers with floating gear and seed. Farmers paid a $20,000 access fee to the community and were obligated to grow a preset minimum biomass on all leases. In 2023, shellfish farmers harvested 1.43 million oysters from 0.6 ha. The community used a peer-reviewed science finding that each oyster harvested removed ~0.28 gN. Thus, in 2023, a total of ~400 kgN was removed from ~0.6 ha of oysters. N removal by oysters offset ~$4.5 million in costs for new sewer infrastructure and harvests produced ~$350,000 in revenue.

Restorative shellfish aquaculture removes nutrients *in situ* already present, while UD prevents new nutrients from entering aquatic systems. Citing 2023 data scientists calculated that some N-impaired estuaries from septic leachates would not require expensive sewering or alternative septic systems at all. Although UD alone could meet nutrient reduction goals, restorative shellfish aquaculture improved water quality and would help reduce capital investments. Restorative shellfish aquaculture and UD would be much more rapidly implemented and would improve aquatic ecosystems sooner than the decades-to-implement sewers and septic systems.

Alternative, integrated ecological approaches to aquatic ecosystem restoration are nature-based solutions that create new community revenues, jobs, produce nutritious, tasty foods, and recover valuable fertilizers. They use fewer natural resources, are more environmentally beneficial and sustainable than conventional solutions, less expensive, and would avoid future, very large GHG emissions. A nature-based solution incorporating shellfish aquaculture and UD demonstrates how homeowners and coastal communities can work together to better accomplish environmental restoration and provide an alternative to investments in capital intensive sewer/septic systems being promoted worldwide as the sole solution to our aquatic/coastal crisis.

**Introduction**

The host nutritional status can be included among the significant aspects that influence immune responses, modulating the resistance to infection (Kiron, 2012). Nutrition can have substantial health implications for animals. Particularly in fish, best practices on diet formulation are of significant importance, as feeds probably represent the most lavish operational expenditure to the aquaculture industry (Trichet, 2010). Nutritional intervention can be a critical component of disease prevention or an essential aspect of disease management, and microalgae can be vital functional ingredients. The term "functional feed" describes fish feeds that have added benefits beyond the fish essential nutritional requirements. As the health status and growth are expected to be improved by consuming these functional feeds, a shift away from chemotherapeutic and antibiotic treatments would be possible. While many additives or feed ingredients derived from microalgae are available for inclusion in functional feeds, little attention has been paid to the role of *Euglena gracilis* as potential immunomodulator during fish early live stages. In fact, *E. gracilis* produces high levels of β-1,3-glucan, omega-3 fatty acids, protein, and vitamins C and E. The present study aimed to assess the immunomodulatory potential of dietary *E. gracilis* inclusion in diets for European seabass (*Dicentrarchus labrax*).

**Methodology**

European seabass juveniles (initial average weight 10.7±1.2 g) were fed five isoproteic and isolipidic experimental diets for two weeks. A-H and A-L: *E. gracilis* (strain A) broken cells at high or low concentrations, respectively; and B-H and B-L: *E. gracilis* (strain B) extract in combination with a carbohydrate-rich residue at high or low concentrations, respectively. At the end of the feeding trial, seabass from all dietary treatments were submitted to two different bacterial challenges by either inoculating *Photobacterium damselae piscicida* (*Phdp*) into the peritoneal cavity, or bath challenged with *Tenacibaculum maritimum* for 2 hours in aerated seawater. Following infection, blood and tissues (head-kidney, liver, gut, and skin) were collected after 24 hours for assessing haematological and immune parameters, oxidative stress, and gene expression. Cumulative mortality was followed for 12 days.

**Results**

Results from the present study showed a similar host response to both infection models regardless dietary treatments. Indeed, leukopenia was observed in all infected fish as a result of white blood cells migration to the sites of pathogen inoculation. In contrast, haematological parameters such as haematocrit and red blood cell counts increased at 24 hours due to host increased oxygen demands during the inflammatory response. Although no significant changes in disease resistance were observed due to dietary treatments, seabass fed A-H and B-L diets tended to be more resilient to *Phdp*. Similarly, dietary treatments were able to delay disease progression after infection with *T. maritimum*.

*(Continued on next page)*

European seabass fed A-L dietary treatment showed higher plasma peroxidase levels compared to their counterparts fed B-L at 24 h following infection with *Phdp*, while the opposite pattern was observed after infection with *T. maritimum*, with lower plasma peroxidase activity in fish fed A-L compared to those fed the control diet. Hepatic oxidative stress biomarkers were not modulated by dietary treatment after infection with *Phdp*. However, an increase in lipids peroxidation was observed in seabass fed A-H compared to those fed the control diet after infection with *T. maritimum*. Gene expression data also showed a modulatory effect of dietary treatments after infection. In particular, European seabass fed the B-H diet showed highest transcripts of several immune-related genes at local level (i.e., mucosal tissues) after infection with *T. maritimum*.

**Conclusion**

Dietary supplementation of *E. gracilis* bioactive compounds seems to modulate immune and oxidative stress responses in European seabass submitted to different infection models (i.e., intraperitoneal injection and bath inoculation). Data from the present study suggest great potential for the development of functional feeds using *E. gracilis* bioactive compounds. Further studies are required to investigate other feeding times as well as more diverse bioactive compounds concentration in aquafeeds.

# ENHANCING STEM EDUCATION THROUGH XR-INTEGRATED AQUAPONICS: FINAL RESULTS FROM THE XRAqua PROJECT

João Cotter*

Aquaponics Iberia
Av. Tenente Valadim, 17, 2.F
2560-275 Torres Vedras, Portugal
Email: joao.cotter@aquaponicsiberia.com

## Introduction

XRAqua is a pioneering educational project that merges real-world aquaponics systems with an interactive virtual reality (VR) application to enhance STEM education through immersive, data-driven experiences. The project addresses the urgent need for innovative pedagogical approaches linking sustainability, aquaculture, food production, and digital technologies in secondary education, while raising awareness of low-trophic aquaculture solutions.

## Methodology

Throughout the 2024/2025 school year, a fully operational freshwater aquaponics system was installed at Madeira Torres Secondary School (Portugal), incorporating the cultivation of fish species alongside hydroponic vegetable production in a closed-loop design. Students interacted with the physical system and its digital twin via a dedicated XR application, allowing them to monitor parameters (e.g., temperature, pH, dissolved oxygen, electrical conductivity) using IoT sensors connected to an interactive dashboard, perform maintenance simulations, and engage with gamified sustainability challenges. User acceptance, educational impact, and system usability were systematically assessed through surveys, quizzes, and system data analytics.

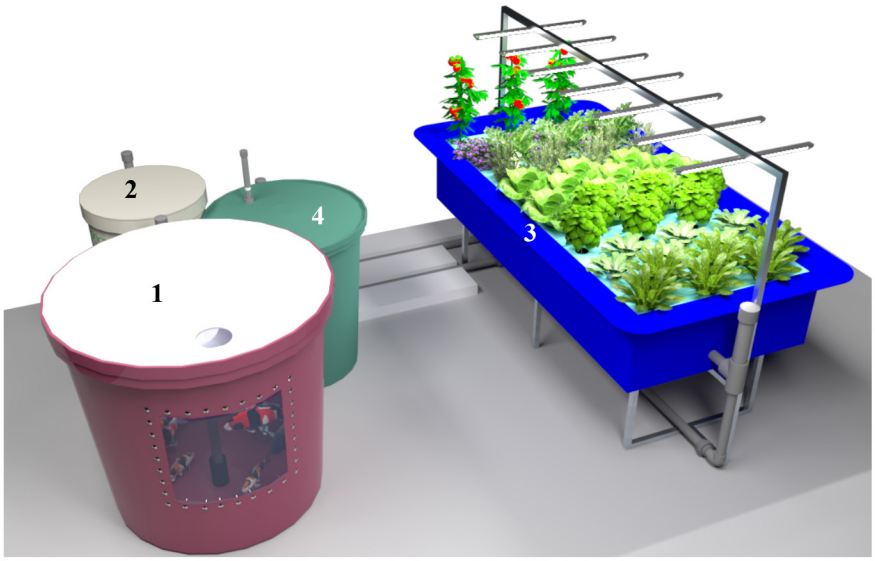

Fig. 1 - 3D perspective of the aquaponics system installed in the school, including: 1. 500 L fish tank, 2. Radial flow settler, 3. Hydroponic grow bed, and 4. Biofilter and water pump.

*(Continued on next page)*

**Results**

By September 2025, XRAqua will have completed its implementation phase, with comprehensive datasets gathered from more than 150 students across scientific, technological, and environmental disciplines. Preliminary findings demonstrate notable improvements in students' scientific literacy, critical thinking, and understanding of sustainable aquaculture practices. Over 85% of participants reported higher motivation towards STEM subjects, and significant increases were recorded in knowledge acquisition related to fish physiology, water quality management, and circular food systems. The XR platform achieved high usability ratings, and real-time data visualization via the online dashboard was pivotal in maintaining student engagement. Fish survival and growth rates in the pilot system were consistent with expected performance benchmarks for small-scale educational aquaponics setups, validating the technical feasibility of integrating aquaculture training into secondary school curricula.

**Conclusion**

XRAqua confirms the potential of combining XR technologies with aquaponics and fish farming as an effective educational strategy to foster sustainability awareness and build future competencies in aquaculture. The project's outcomes suggest that such hybrid learning models can be successfully scaled across educational settings, bridging gaps between theoretical knowledge, hands-on practice, and digital innovation, while contributing to broader blue economy and food security objectives.

# EFFECTS OF SINGLE AND COMBINED MICROALGAE ON LARVAL GROWTH, DEVELOPMENT AND SURVIVAL OF THE SEA CUCUMBER *Holothuria arguinensis*

G. Courtois de Viçose*, N. Marrero, J. M. Afonso López

Instituto ECOAQUA/GIA Universidad De Las Palmas De Gran Canaria
Juan de Quesada 30

Email: gtricor@hotmail.com

## Introduction

The overexploitation of wild sea cucumber stocks calls for sustainable aquaculture to meet demand and aid conservation (Purcell et al., 2012). *Holothuria arguinensis*, valued for its commercial potential and facing population declines, is a strong aquaculture candidate (Domínguez-Godino & González-Wangüemert, 2020). Production success depends on optimizing larval rearing, particularly microalgal diets with suitable nutritional profiles to support growth, development and survival (Domínguez-Godino & González-Wangüemert, 2019; Sibonga et al., 2021). In related species like *H. scabra* and *Apostichopus japonicus*, diets rich in protein, lipids, and essential fatty acids (EPA, DHA) have improved larval performance (Duy et al., 2016; Sibonga et al., 2021). Despite these advances, the role of microalgae such as *Rhodomonas* (Yamamoto et al., 2015) in *H. arguinensis* have not been thoroughly investigated, and understanding the link between algal composition and larval development is essential for refining hatchery protocols. This study aims to evaluate the effects of *Rhodomonas* sp. and *Isochrysis* sp. diets, on the growth, development, and survival of *H. arguinensis* larvae to contribute to the development of effective feeding strategies for its aquaculture.

## Material and methods

*Broodstock, larvae and microalgae diets*

Adult specimens of *H. arguinensis* were induced to spawn by thermal stimulation. At 24 h post-fertilization, larvae were stocked at 0.75 eggs/mL in 200 L conical tanks with 1 µm filtered, UV-sterilized seawater, renewed daily by 50%. Triplicate 50 mL samples were taken twice weekly for four weeks to monitor larval stages. Ten larvae per replicate were photographed upon stage transitions, with length and width measured using ImageJ Software. Larvae were fed daily with either a mixed diet of *Rhodomonas* sp. and *Isochrysis* sp. (5000 cells/mL each) or *Isochrysis* sp. alone (10,000 cells/mL). *Isochrysis* sp. microalgae were cultured in 5 L glass flasks and *Rhodomonas* sp. in 20 L polyethylene bags, both using sterilized seawater with F/2 medium (Guillard, 1975), under a 16:8 h light : dark cycle at room temperature. Cultures were harvested and counted daily using a Neubauer chamber.

*Biochemical analysis*

Proximate analysis of the microalgae was conducted using standard procedures (AOAC, 2023) and fatty acids analysis and identification was performed according to the protocols of Duy et al. (2016).

## Results and discussion

Unlike the findings of Duy et al. (2016) and Sibonga et al. (2021), no significant differences in auricularia larval length were observed across treatments from day 3 to 28 ($P > 0.05$). However, larvae were generally larger than those reported for *H. arguinensis* in previous studies (Domínguez-Godino & González-Wangüemert, 2019; Sousa et al., 2023). Late-stage auriculariae fed a mixed diet including *Rhodomonas* sp. were longer (1002.42 ± 148.59 µm) and significantly wider (744.31 ± 130.57 µm) than those fed *Isochrysis* sp. alone (981.71 ± 130.97 µm; 664.29 ± 116.88 µm). This may reflect the higher protein and EPA, and lower lipid content of *Rhodomonas* sp. (Tables 1 & 2), previously linked to enhanced larval performance (Duy et al., 2016). Its inclusion also significantly improved survival at days 14 and 21 (62.11 ± 3.65% and 41.33 ± 2.41%) compared to *Isochrysis* sp. (40.44 ± 2.91% and 26.66 ± 10.07%), and accelerated the appearance of the doliolaria and juvenile stages by 10 days.

**Introduction**
Smoltification represents a critical developmental transition in Atlantic salmon (*Salmo salar*) aquaculture, with successful adaptation to seawater directly impacting production outcomes. Despite its importance, the molecular mechanisms underlying this complex physiological transformation remain incompletely understood. This study employed a comprehensive proteomic analysis to elucidate the temporal progression of protein expression changes during smoltification to inform targeted nutritional strategies.

**Methods**
Blood samples were collected from a single cohort of Atlantic salmon at four developmental stages: pre-smolt, smolt, 3-week post-smolt, and 3-month post-smolt. Proteomic analysis identified ~ 3,500 proteins per sample, with 2,588 proteins retained for differential expression analysis. Principal Component Analysis (PCA) was performed to distinguish developmental stages based on proteome signatures. Weighted correlation network analysis (WGCNA) identified protein modules with stage-specific expression patterns. Gene Ontology (GO) and KEGG pathway enrichment analyses characterised the biological processes and pathways altered during each developmental transition.

**Results**
PCA revealed distinct proteome signatures for each developmental stage, with PC1 (11.1%) primarily separating pre-smolt/smolt from post-smolt stages (Fig. 1). WGCNA identified seven distinct protein modules with stage-specific expression patterns showing moderate to weak correlations (-0.16 to 0.12) with developmental stages, indicating complex regulatory networks underlying the smoltification process. Six modules demonstrated highly significant ($p < 0.001$) differences in expression across developmental stages.

The pre-smolt to smolt transition was characterised by extensive transcriptional reprogramming, with significant enrichment of RNA splicing (FDR < 1.0e-45) and spliceosome pathways (FDR < 1.0e-40). This stage also showed activation of necroptosis and NOD-like receptor signalling pathways, indicating immune system involvement in initial adaptation. The MEgreen module exhibited the highest expression in smolt stage (0.122 ±0.077), suggesting involvement in smoltification-specific processes.

The smolt to 3-week post-smolt period revealed marked upregulation of translation (FDR < 1.0e-64) and ribosomal processes (FDR < 1.0e-85), indicating intensive protein synthesis. This transition was characterised by significant enrichment of carbon metabolism, oxidative phosphorylation, and tight junction pathways essential for osmotic regulation. The MEbrown module peaked at the 3-week post-transfer stage (0.095 ±0.022), showing inverse correlations between pre-smolt (-0.15) and post-transition stages, suggesting involvement in seawater adaptation processes.

The final transition to 3-month post-smolt involved upregulation of protein quality control mechanisms, including protein folding and regulation of proteolysis (FDR < 1.0e-11). Phagosome pathways showed the highest enrichment (FDR < 1.0e-11), alongside necroptosis and protein processing in the endoplasmic reticulum. The MEred and MEyellow modules showed the strongest positive correlation with the 3-month post-transition samples (0.12), indicating involvement in long-term seawater adaptation mechanisms.

*(Continued on next page)*

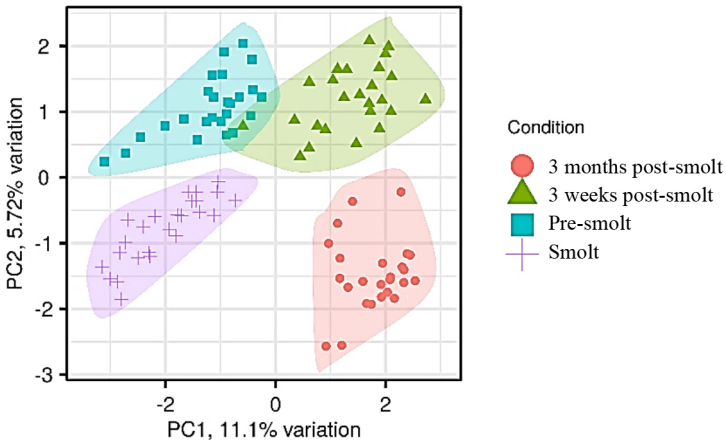

**Fig 1.** Principal Component plot of the blood proteome samples from the four stages of smoltification. Separation is most pronounced along PC1, with the post-smolt on the positive side and pre-smolt and smolt on the negative side.

**Discussion**

This study reveals that smoltification requires substantial energetic investment and precise protein regulation, evidenced by coordinated expression of energy metabolism modules (MEyellow, MEred) and protein homeostasis modules (MEturquoise, MEgreen, MEbrown) across different developmental stages. The significant upregulation of translation and ribosomal processes during the smolt to post-smolt transition suggests this period represents a critical window where nutritional support for protein synthesis could enhance adaptation success. These findings align with previous studies reporting increased protein synthesis in Atlantic salmon during smoltification but provide a more comprehensive temporal characterisation of the process.

The concurrent activation of immune-related processes throughout smoltification, particularly complement activation and NOD-like receptor signalling pathways, suggests that immune system modulation is an integral component of the adaptation process rather than a secondary response. This finding has important implications for feed formulation, suggesting that immunostimulants or immune-supporting nutrients might be beneficial during smoltification. The enrichment of tight junction pathways during seawater transition further emphasises the importance of intestinal barrier function in osmotic adaptation, pointing to potential benefits of dietary components that support epithelial integrity. Additionally, the enrichment of cellular detoxification and stress response pathways in later stages suggests potential benefits from antioxidant supplementation during long-term seawater adaptation.

This proteomic analysis provides a detailed molecular framework for understanding smoltification in Atlantic salmon, highlighting critical periods of metabolic demand and protein synthesis that could be targeted with specific nutritional strategies. These findings may inform the development of stage-specific feed formulations to support the substantial energetic and metabolic requirements revealed during the smoltification process, potentially improving production outcomes in salmon aquaculture.

# SEX-RATIO AND SEXUAL DIMORPHISM IN THREE NATURAL POPULATIONS OF EUROPEAN SEABASS *(Dicentrarchus labrax)* EXPOSED TO FOUR THERMAL REGIMES

D. Crestel*, A. Vergnet, E. Delpuech, N. Sanchez-Baizan, F. Clota, M.O. Blanc, S. Lallement, F. Moulard, F. Ruelle, T. Navarro, D. McKenzie, F. Allal, M. Vandeputte

E-mail: damien.crestel@inrae.fr

**Introduction**

With global warming, the surface temperature of the Mediterranean Sea has increased by 0.4 °C per decade from 1985 to 2006 (Nykjaer, 2009) and is projected to increase further by 2.2 to 3.4 °C until 2080 (IPCC, 2021). The European seabass, *Dicentrarchus labrax*, is very important for both aquaculture and fisheries in the Mediterranean. One of the big challenges in seabass farming is to improve the sex ratio in favour of the females, which grow faster and mature later. Moreover, seabass has a polygenic sex determination system with environmental influences, mainly driven by temperature (Vandeputte and Piferrer, 2019). Therefore, studying the impact of changing temperature on sex ratio is crucial for seabass production. In this study, we investigated the sex ratio and sexual dimorphism of three natural populations: Atlantic (AT), Western Mediterranean (WM) and Eastern Mediterranean (EM) in different thermal regimes.

**Materials and Methods**

The production of the three populations was achieved using three different full factorials with 30 sires per population and 7, 14 and 11 dams for the AT, WM and EM populations, respectively. Until 20 days post-hatching (dph), the populations were reared separately at 13°C in 2 replicate tanks per population. From 20 dph, the populations were mixed in equal proportions and placed in four thermal regimes that mimic the temperatures encountered in the Atlantic (*rAT*, annual average = 13.8 °C, min = 10.4 °C, max = 18 °C), the western Mediterranean Sea (*rWM*, annual average = 16.6 °C, min = 12.6 °C, max = 22.5 °C), the eastern Mediterranean Sea (*rEM*, annual average = 21.7 °C, min = 16.8 °C, max = 27.6 °C) and a temperature favouring females applied in aquaculture (*rAQUA*, 16 °C until 70 dph, 23 °C from 70 to 120 dph and then an eastern Mediterranean temperature regime). At a weight of 10 g, 6230 fish were tagged, weighed and genotyped with the Axiom™ Seabass 57k SNP DlabChip array. To recover the pedigree and population of each fish, parentage assignment was performed by exclusion using a subset of 1000 markers with the APIS R package (Roche et al., 2024)key issues are genotyping errors and an absence of parent genotypes because of sampling, traceability or genotyping problems. Most likelihood-based parentage assignment software programs require a priori estimates of genotyping errors and the proportion of missing parents to set up meaningful assignment decision rules. We present here the R package APIS, which can assign offspring to their parents without any prior information other than the offspring and parental genotypes, and a user-defined, acceptable error rate among assigned offspring. Assignment decision rules use the distributions of average Mendelian transmission probabilities, which enable estimates of the proportion of offspring with missing parental genotypes. APIS has been compared to other software (CERVUS, VITASSIGN, with two allelic mismatches tolerated. Each fish was sexed by macroscopic examination of the gonads at slaughter which occurred between 1 and 3 years of age in different fish groups. Threshold genomic models using the blupf90 suite of programs and the genomic relationship matrix were used to estimate heritabilities and genetic correlations, and to assess genotype-by-environment interaction (GxE) of sex between regimes.

**Results**

5704 fish were unambiguously assigned to their parents and sexed as a male or a female. A significant interaction was observed between thermal regime and population on sex ratio. For each population, significantly less females were observed in *rAT* than in the other regimes ($P < 1e\text{-}04$). For the WM population, significantly less females were observed in *rWM* than in *rAQUA* ($P < 1e\text{-}04$). In each thermal regime, there were more females in the AT population compared to WM and EM. For the warmer regimes (*rEM* and *rAQUA*), all populations were significantly different from each other, and WM had more females than the EM population (Fig. 1). Globally, the sex ratios of the AT population were balanced with an average of 46.9 % of females whereas the ones for Mediterranean populations were biased toward males, even more in colder regimes (*rAT* and *rWM*).

*(Continued on next page)*

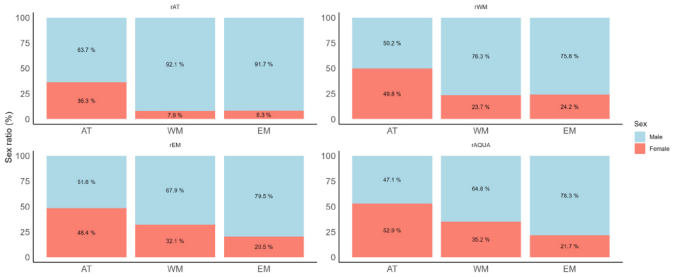

Fig. 1 - Sex ratio of three populations (AT = Atlantic, WM = Western and EM = Eastern Mediterranean) of European seabass in four thermal regimes (rAT = Atlantic, rWM = West-Med, rEM = East-Med and rAQUA = aquaculture regimes) since 20 dph.

A 3-way interaction between regime, population and sex was significant for body weight at the time of tagging (≈ 10 g, P = 1.19e-04), meaning that the sex dimorphism differed among populations and thermal regimes. In colder regimes (*rAT* and *rWM*), no interaction was found between sex and population and females were 28.5 % heavier than males on average. In the warmer regimes, the interaction between sex and population was significant (P < 8.08e-04). The difference in weight between females and males was stronger for the AT population (> 50 %) compared to Mediterranean populations (33-42 %). The heritability of sex was similar between AT and EM populations, averaging 0.64 ± 0.07. Further analyses will be presented, especially regarding GxE for sex-ratio..

## Discussion

The results confirmed that the sex of European seabass is strongly influenced by temperature but also has a strong genetic basis, showing for the first time a population effect with the AT population producing more females. We also showed that the sexual size dimorphism of body weight in favour of females depended on population and thermal regime with higher sexual dimorphism of body weight for the AT population in warmer regimes (*rEM* and *rAQUA*). Globally, we decrypted two groups of thermal regimes with one represented by *rAT* having temperatures below 13 °C until 50 dph and one represented the other thermal regimes. Indeed, the *rAT* had sex ratio more biased toward males than the other thermal regimes for the three populations and confirmed that a long lasting of cold rearing temperature promote the proportion of males (Vandeputte et al., 2020). Further analyses will describe why AT population expressed higher proportion of females with the results of heritability and genetic correlations but also studying the sex determination QTLs between the populations. This study is part of FishNess project (ANR-21-CE20-0043).

**Introduction**

Aquaculture boom brings about new challenges such as bacterial and viral outbreaks. In this context, finding new molecules with no negative impact for the host neither the environment become an urgent issue. Antimicrobial peptides (AMPs) have arisen as potential candidates as treatments in aquaculture due to their properties and functions (Katzenback, 2015). Focusing on their direct role against pathogens, AMPs possess great bioactivity against a wide range of microbes including bacteria and viruses with relevance in mariculture. Among AMPs, we can find beta-defensin (Bdef) peptides, which have demonstrated antibacterial and antiviral activity in several species (Das et al., 2022). However, these roles for Bdef derived from European sea bass (*Dicentrarchus labrax*) have not been evaluated yet. Thus, the objective of this work was to assess the antiviral and antibacterial activities of (Bdef1 and Bdef2 derived from European sea bass, reduced or oxidated, against the most relevant viruses and bacteria for aquaculture.

**Material and methods**

European sea bass Bdef1 (4903 and 4904) and Bdef2 (4905 and 4906) mature peptides were synthesized by solid phase multiple peptide system using the Fmoc/tBu strategy (Houghten, 1985). Peptides were lyophilized and analyzed by MALDI-TOF mass spectrometry. The antibacterial activity of the four synthetized peptides was determined by evaluating the bacterial growth curves of *Vibrio harveyi*, *Vibrio anguillarum* and *Photobacterium damselae* using a method that was previously described (Sunyer & Tort, 1995). Bacteria was incubated with different dilutions of each peptide (0.6, 2.5 and 10 μg/mL). Data were expressed as the % of bacterial growth inhibition. Otherwise, the antiviral activity of the four synthetized peptides against RGNNV, SJNNV/RGNNV, RGNNV/SJNNV, EVEX, EVE, IPNV, SVCV and VHSV was performed following a previously described method with modifications (León et al., 2020). E-11 or EPC cells were seeded in 96-well plates until the 60-80% confluence. Equal volumes of different viral stocks were incubated with 500 μg/mL of the peptide during 24 h at the optimal temperature of each virus.

**Results**

The antibacterial effects of Bdef differed according to the tested bacteria. Inhibition rates of *V. harveyi* increased with the doses of reduced Bdef peptides whilst were decreased for oxidized ones. Otherwise, reduced Bdef1 or oxidated Bdef2 exerted the greatest growth inhibition against *P. damselae*. Contrary to this, for *V. anguillarum*, the activity for all peptides was very low and, in some cases, undetectable.

The oxidized Bdef peptides showed similar or higher antiviral activity. Also, differences between both Bdef1 and Bdef2 were observed. For instance, Bdef1 showed highest activity against RGNNV, SJNNV/RGNNV, IPNV, SVCV and EVEX, followed by VHSV, with no activity against EVE, while Bdef2 peptides exerted highest antiviral activity than Bdef1 against VHSV and EVE but lowest against RGNNV, SJNNV/RGNNV, IPNV, SVCV and EVEX. Surprisingly, RGNNV/SJNNV and TiLV were completely resistant to both Bdef peptides.

*(Continued on next page)*

**Discussion and conclusions**

Since oxidation process to establish disulfide bonds in peptides is so difficult, in this project we evaluated the differences between oxidated and reduced forms of Bdef peptides. The benefits of generating reduced transcripts includes reduced costs and faster synthesis but the alteration in secondary structure must be considered (Yang et al.,2017). Bdef disulfide bridges are tightly related to their bioactivity and the previous studies have not reach a clear conclusion yet (Schroeder et al., 2011; Yang et al., 2017). Our results from the antiviral trials pointed to oxidated peptides as more potent antiviral molecules in most cases while data from antibacterial assays revealed that oxidated peptides were more effective in lower doses than reduced peptides. Therefore, oxidation process might be necessary for European sea bass to be bioactive. Otherwise, when comparing the effects of Bdef1 on the bacterial growth or viral replication only were higher than those derived from Bdef2. In conclusion, European sea bass Bdef1 oxidated peptides could be postulated as potential tools to prevent or treat bacterial and viral infections in European sea bass farms.

**Introduction**

In the pursuit of sustainable solutions for aquaculture, there is increasing interest in identifying natural sources and their potential applications. Polychaetes, which are attracting great environmental attention, have arisen as potential solutions in aquaculture in two ways: they could be used as bioremediation agents of the aquaculture by-products as well as alternative fish and crustacean food sources (Pombo *et al*. 2018; Wang *et al*. 2019; Yang *et al*. 2022). In addition, their feasibility to grow in rich microbial environments and their ecological adaptability suggest they may harbour potent innate immune activities (Berlov and Maltseva 2016) such as antimicrobial peptides and other immune effectors (Joo *et al*. 2020). These activities could enhance, by one side, the removal of fish pathogens in aquaculture, and by the other, increasing the nutritional and immunological value when used as functional feed ingredients.

**Material and methods**

Juvenile *Perinereis vallata* polychaetes underwent a 35-day feeding with a commercial diet (Control) and three experimental groups fed with at 5%, 10%, and 20% Atlantic salmon sludge (Salmones Austral S.A.) as elsewhere (Gómez *et al*. 2023). All specimens were dehydrated at 60 °C, homogenised in PBS (pH 7.2) and supernatants obtained by centrifugation. Their immune and antimicrobial capacity were determined (León *et al.* 2020; Valero *et al*. 2023). Data were represented as the mean per group ± standard error of the mean ($n = 3$) and significance analysed by Student t test ($p < 0.05$) comparing experimental with Control group.

**Results and discussion**

A previous study already demonstrated that *Perinereis sp.* fed with salmon sludge increased their growth, survival, nutrient assimilation and removed total organic matter (Gómez *et al*. 2023). Our findings revealed that control polychaetes exhibited marked protease, antiprotease and antibacterial activities, effectively inhibiting the growth of several bacterial species. Specifically, control extracts suppressed bacterial proliferation by approximately 45-54% in *Vibrio harveyi* and *Aeromonas salmonicida*, and by 14% in *Photobacterium damselae*. In contrast, polychaetes fed with sludge, regardless of the proportion, showed a reduced ability to inhibit bacterial growth. Additionally, *Tenacibaculum maritimus*, an emerging salmonid pathogen recently reported in Chile (Apablaza *et al.* 2017), demonstrated enhanced growth when incubated with polychaete extracts. Additionally, we assessed the potential antiviral activity of *P. vallata* extracts.

**Conclusion**

This study demonstrates that polychaetes exhibit robust antiprotease, protease and direct antipathogenic activities, evidenced by their bacteriostatic effects against fish pathogens. These functions might be regulated by dietary inclusion of salmon sludge. Therefore, these polychaetes might be promising not only as bioremediation agents but also as natural sources of bioactive compounds for fish aquaculture. Their inclusion in fish diets may transfer immune effectors that enhance host immunity and resistance to infections. Thus, beyond their nutritive value, the immune-stimulating properties of polychaetes may provide an added functional benefit, reinforcing their potential as innovative antipathogenic and immunostimulant feed additives for sustainable aquaculture practices.

**Introduction**

The aquaculture industry is rapidly expanding, demanding effective disease prevention strategies. European seabass (*Dicentrarchus labrax)*, a key Mediterranean species, faces significant disease challenges (FAO, 2023). Functional feeds, particularly those incorporating microalgae, offer a promising and sustainable approach to enhance fish health and immunity. Microalgae such as *Tetraselmis chui* are rich in beneficial compounds including proteins, essential fatty acids, carotenoids, and other bioactive molecules, which contribute to improved growth, immune function, and disease resistance (Sansone et al., 2017). Additionally, other microalgae sources are known for their β-glucan content, further highlighting the diverse benefits of microalgae inclusion in aquafeeds. This study investigates the effects of dietary *T. chui* extracts and microalgae derived β-glucans on the immune response of European seabass and their resistance to a bacterial pathogen, after a short feeding boost of 5 and 14 days.

**Materials and methods**

European seabass juveniles (14.16 ± 1.01 g) were randomly assigned to triplicate tanks based on dietary treatments. Five experimental diets were formulated: a control diet based on a commercial formulation tailored to fulfill the dietary requirements of European seabass (CTRL), the control diet supplemented with a high dose of *T. chui* extract (Diet 1), the control diet supplemented with a low dose of *T. chui* extract (Diet 2), the control diet supplemented with microalga-derived β-glucans (Diet 3) and the control diet supplemented a commercially available product (CTRL+). Fish were fed the experimental diets for 5 and 14 days, after which they were sampled. At the end of each feeding period, the remaining fish were intraperitoneally injected with *Photobacterium damselae* subsp. *piscicida* strain MT1415 ($2.75 \times 10^5$ CFU/mL), and sampled 6 hours post infection. Samples from the gut, head-kidney, plasma, and liver were collected, in both sampling points. Mortalities were monitored over the following 8 days to assess disease resistance. In order to evaluate the effects of the dietary treatments and feeding period, a principal component analysis (PCA) followed by a canonical discriminant analysis (CDA) were employed, to obtain a systemic overview of the differential modulation, between feeding times and dietary treatments. Further analysis with ANOVA statistical test was employed at each sampling point and for each feeding time. The response to infection was also evaluated by a PCA and CDA. Mortalities were evaluated with Kaplan-Meier and Mantel-cox tests.

**Results and Discussion**

Feeding the animals for 5 and 14 days the experimental diets, generated a considerably different modulation of the immune status of European seabass, inciting the importance of carefully evaluating duration of feeding of functional feeds. Contrarily to previous observations by Reis et al. (2021), a short-term (5 days) supplementation with β-glucan (Diet 3) increased liver lipid peroxidation after infection. Meanwhile, this same diet applied for a longer period (14 days) led to lower cortisol levels and boosted key antioxidant enzymes, suggesting a later enhanced resilience to stress while improving oxidative status. The inclusion of *T. chui* extract showed a dose-dependent effect with the higher dosage (Diet 1) remarkably reducing gut lipid peroxidation in non-infected fish, highlighting its described potent antioxidant properties (Randazzo et al., 2023). In contrast, at lower dosage (Diet 2), the microalgae dietary inclusion, resulted in a less favourable oxidative stress profile and less noticeable immune modulation. Finally, diets and feeding duration did not significantly alter the survival of European seabass juveniles in response to the bacterial challenge.

*(Continued on next page)*

Altogether, these findings suggest that supplementing both *T. chui* extracts and β-glucans in European seabass diets for a short period of 14 days prior to an acute stress, may be a positive prophylactic strategy. The results underscore the importance of both dosage and feeding duration for optimizing the benefits of these functional ingredients in aquaculture.

**Introduction**

Aquaculture production has rapidly grown in recent years, accounting for 51% of the global fish production in 2022 (FAO, 2024). To meet the increasing demand for seafood, sustainable aquaculture practices represent a promising alternative to traditional systems, as they face several environmental and biological issues (Taşbozan, 2023). One of the most important challenges in aquaculture is ensuring fish welfare, which is typically assessed through a global set of parameters, including physiological indicators measured in blood and plasma, which are among the most widely used. However, procedures such as blood sampling are invasive and may provoke additional stress, potentially compromising the animal's well-being (Carbajal et al., 2019). In this context, skin mucus has been increasingly used as an alternative non-invasive method to assess fish welfare indicators. Yet, only a few studies were conducted on Gilthead seabream (*Sparus aurata)*, focusing on a limited range of parameters (Guardiola et al., 2016; Fernández-Alacid et al., 2018). Moreover, limited attention has been given to correlations and temporal dynamics between parameters measured in both plasma and mucus matrices. Therefore, this study aims to determine whether skin mucus can be used as a valid non-invasive alternative to plasma for welfare assessment in farmed Gilthead seabream, by evaluating both mucus-plasma correlations and temporal trends of a set of six physiological indicators (i.e. glucose, lactate, cortisol, total protein, albumin and IgM) related to stress and immunity response of the fish in these two biological matrices.

**Materials and methods**

All procedures involving animals were performed following Italian national legislation (D. lgs. 26/2014) and EU recommendation (Directive 2010/63/EU), with Health Ministry authorisation number code n° 522/2023-PR. Two commercial offshore Gilthead seabream farms located in northern Sardinia (Italy), hereafter referred to as sites A (organic farm) and B (conventional farm), were selected for this study. Fish (average weight: 380 ± 24 g; total n = 30) were sampled for plasma (blood sampling) and skin mucus at two time points after anesthesia: T0 (August 2024; n = 10 at site A) and T1 (May 2025; n = 10 per site). Prior to laboratory analysis, both blood and mucus samples were centrifuged to obtain plasma and mucus supernatant, respectively, which were both frozen at -20 °C until use. Glucose, lactate, cortisol, total protein, albumin and IgM were measured in both plasma and skin mucus using commercial kits, following the manufacturer's instructions. Statistical analyses were carried out using R software (version 4.5.0). Spearman correlation was used to evaluate the relationship between welfare indicators derived from the different matrices. The permutation-based linear model was used to assess temporal trends in glucose, lactate, cortisol, and total protein levels across plasma and skin mucus, as albumin and IgM were excluded from this analysis due to insufficient data at T0.

**Results**

Glucose, lactate, cortisol, total protein and albumin levels did not show a significant correlation between plasma and skin mucus samples. In contrast, a significant positive correlation was observed in IgM levels between skin mucus and plasma ($r = 0.558$; $p = 0.009$). The results of the permutation-based linear model showed a significant Matrix × Time interaction ($p < 0.05$) for glucose, lactate and cortisol contents, indicating different temporal dynamics between plasma and skin mucus. These physiological indicators remained constant over time in skin mucus, while changes were observed in plasma. Particularly, plasma lactate levels approximately doubled over time, while glucose and cortisol contents in plasma decreased by about 45% and 89% between T0 and T1, respectively. In contrast, no significant Matrix × Time interaction ($p > 0.05$) was observed for total protein, suggesting a similar temporal trend between both biological matrices. Specifically, total protein in T1 increased by about 21% from T0, regardless of the biological matrix.

*(Continued on next page)*

**Discussions**

Although total protein levels showed a similar temporal trend in both plasma and skin mucus, no significant correlation was found between these two biological matrices. This contrasts with the findings of Fernández-Alacid et al. (2019), who reported a significant correlation between plasma and skin mucus protein levels in meagre (*Argyrosomus regius*), suggesting potential species-specific differences or limited statistical power due to sample size. In fact, a significant positive correlation was found in IgM levels between plasma and skin mucus, indicating similarity in systemic and mucosal physiological dynamics. However, no similar temporal trends or mucus-plasma correlations were found in glucose, lactate and cortisol levels, contrasting with the findings of Fernández-Alacid et al. (2019) in meagre and thus supporting species-specific differences. As hydrophilic molecules, the stability of glucose and lactate over time may indicate their dispersion within the surrounding water, while the differences observed for cortisol support the findings of Guardiola et al. (2016), who reported a delay between the measurement of plasma and skin mucus cortisol in Gilthead seabream, suggesting different systemic and mucosal physiological dynamics.

**Conclusion**

These results suggest that skin mucus can be used as a potential non-invasive proxy to assess some particular welfare indicators (i.e. total protein, IgM) in farmed Gilthead seabream. However, the set of parameters evaluable in skin mucus is limited compared to those in plasma. Therefore, further studies with larger sample sizes, as well as exploration of physiological mechanisms behind molecular transfer between plasma and skin mucus, and the analysis of additional indicators, are needed to support these preliminary findings.

# SALMON LICE DISLODGED IN DELOUSING OF FARMED SALMON CAN SURVIVE AND REATTACH TO NEW FISH

**Introduction**: Sea cages used in Atlantic salmon aquaculture are open to the environment, leading to infestation by the naturally occurring parasite the salmon louse (*Lepeophtheirus salmonis*). Salmon lice infect the skin of the salmon and delousing treatments to reduce parasite spillover to wild salmon populations dislodges the mobile (preadult and adult) stages of the parasite. Depending on the method and procedures, this can lead to the release of large amounts of lice to the surrounding water. In a natural environment, salmon lice are dispersed to other fish as copepodites, and the question remains whether these later mobile stages of the parasite can survive and spread to new fish?

**Methods**: Dislodged mobile lice were monitored in the laboratory for survival at different temperatures and salinities and ability to attach to new fish. Furthermore, the sinking rates of lice were investigated experimentally in tanks and open water. These results were utilized in a hydrodynamic dispersal model to quantify potential spread to other farm sites.

**Results and discussion**: All mobile lice exhibited long survival off fish with most lice surviving more than one week. Warmer temperatures and lower salinity reduced overall survival. Adult females survived longer than preadults and adult males. Also, lice reattachment to new fish was only slightly reduced even by prolonged removal from the host fish. Whereas the long survival times and high rates of reattachment highlight the risk of reinfestation time, the mobile lice exhibited limited ability to remain in the water column. The rate of sinking was approximately 1metre per minute with the larger adult females sinking faster than the smaller stages. Adult males appeared as stronger swimmers reacting to host cues in the water. Accordingly, modelled dispersal indicates that the highest risk of reinfestation is within farms and to wild fish in the vicinity of cages. Farms in the surrounding area have a much lower risk, but delousing under circumstances with significant water transport to farms downstream should be avoided.

# INITIAL INFESTATIONS OF SEA LICE ON MIGRATING ATLANTIC SALMON POST SMOLT ARE DOMINATED BY *Lepeophtheirus salmonis*

## Introduction

Sea lice (*Caligidae*) are marine ectoparasites of fish that feed on the skin, mucus, and in some species the blood of their host. At high densities, sea lice pose a major health risk to wild and cultured fish. The Atlantic salmon (*Salmo salar*) is a host to *Lepeophtheirus. salmonis* a sea louse species specific to salmonids and *Caligus elongatus* with a very broad host range. Production of *L. salmonis* on farmed fish is heavily regulated in Norway due to parasite spillover to the protected wild Atlantic salmon. Specifically, wild salmonoids are surveilled yearly to assess the threat of *L. salmonis*. Early stages of the two sea lice species (sessile stages) are difficult to distinguish morphologically resulting in unknown contribution by the two species. The purpose of the study was to develop a method to assign species in sessile sea lice and to determine the prevalence of the two species on wild post smolt.

## Methods

Migrating wild salmon which had recently left the freshwater habitat were caught in the outer part of fjords in six locations in Central and Western Norway. Three fjords were sampled for two years resulting in a total of nine samplings. Lice were counted and for the larger mobile stages (preadult and adult) were identified to the species level. For the smaller sessile stages (copepodites and chalimi), lice were sampled in ethanol for subsequent DNA extraction. In the laboratory, sessile lice (n= 1247) were identified as *C elongatus* and *L. salmonis* based on a boiling of samples followed by a species-specific PCR assay. 90% of the samples could be identified using this high-throughput methodology.

## Results and discussion

Given the relatively short timeline between entering their marine phase and when fish were caught, the vast majority (97%) of recorded lice were still sessile. The lice community was heavily dominated by *L. salmonis* which constituted 98 % of all identified sessile lice. The contribution of *C. elongatus* was very low and only exceeded 3 % in two samplings, which also had the overall lowest prevalence and mean abundance of lice. Mobile sea lice were only observed on 6 % of the sampled fish. Of the mobile lice (n= 415), 73 % were identified as *L. salmonis*, and 27 % as *C. elongatus*. Almost all mobile *C. elongatus* came from fish collected in Sognefjorden and Boknafjorden and was similar in both years sampled; 2023 and 2024. In accordance with the life strategy of *C. elongatus* utilizing multiple hosts, we observe a larger proportion of mobile lice of this species. Interestingly, the occurrence of *C. elongatus* appeared to be restricted to two out of six areas investigated in the time period investigated. Overall, we conclude that the sea lice community on migrating Atlantic post smolt in the investigated areas is dominated by sessile lice and that almost all of these lice are *L.salmonis*.

# RUMINAL FERMENTATION AS A BIOTECHNOLOGICAL STRATEGY TO GENERATE PROTEIN INPUTS FOR AQUACULTURE

*E-mail: dantagna@uct.cl,

This study focuses on the development of biotechnological strategies aimed at obtaining alternative ingredients for fish nutrition. The objective was to generate a microbial protein extract from microorganisms in the sheep rumen. To this end, ruminal fluid was inoculated into flasks containing lignocellulosic residues of wheat straw under anaerobic fermentation conditions. The dynamics of bacterial and eukaryotic communities were analyzed before and after the fermentation process. Three ruminal fluid samples and three post-fermentation samples were analyzed using metabarcoding techniques, amplifying the V3-V4 regions of the 16S gene and V9 of the 18S gene. Sequencing was performed on the Illumina MiSeq platform. Bacterial (16S) analyses revealed a high initial predominance of the Bacteroidetes phylum (~70%), followed by Firmicutes (~25%). After fermentation, a notable reduction in the genus Prevotella (from ~60.2% to ~27%) and a significant increase in genera such as Lysinibacillus (from 2% to 22%), Herbinix (from 0.3% to 50%) and Proteiniborus (from 0% to 12.5%) were observed, suggesting a functional adaptation towards lignocellulose degradation and the production of protein-rich microbial biomass. Regarding eukaryotes (18S), an initial dominance of the phylum Ciliophora (~91%) was observed, especially of the genus Entodinium, whose abundance remained stable after fermentation. However, the appearance of representatives of the phylum Oomycota, such as Phytophthora and Peronospora, was detected, indicating a functional diversification possibly associated with the availability of lignocellulose-derived compounds. These results demonstrate that the fermentation of lignocellulosic waste with ruminal microbiota induces significant changes in the microbial structure, favoring the proliferation of taxa with the potential to produce high-protein biomass. This biomass represents a promising candidate as an alternative ingredient for evaluation in aquaculture diets.

# AN INSIGHT INTO FUNGAL COMMUNITY DIVERSITY, ABUNDANCE AND COMPOSITION OF REARING WATER AND RED TILAPIA GILL FROM OPEN RIVER CAGES AND EARTHEN PONDS BY APPLYING INTERNAL TRANSCRIBED SPACER RIBOSOMAL RNA AMPLICON METAGENOMIC SEQUENCING

## Introduction

Aquaculture is crucial in tackling global food security issues where demand for food and economic growth is increasing. Tilapia, the world's second-largest farmed fish, plays a vital role in meeting global demands, particularly in Thailand. Integrating knowledge of mycobiome dynamics with environmental management and aquaculture operations can enhance fish health, water quality, and overall ecosystem stability. It also boosts feed efficiency and lessens the reliance on antibiotics, making this holistic approach essential for sustainable and productive aquaculture systems. While mycobiome research in aquaculture shows great promise, several limitations hinder a complete understanding and practical application. Addressing these limitations requires advancements in technology, more robust experimental designs, and deeper functional investigations to fully grasp the mycobiome's role in aquaculture.

## Materials and methods

Hence, this study, as part of a broader series, aimed to examine the abundance, composition, and diversity of fungal communities in the rearing water and gills of red tilapia cultured in earthen ponds and open river cages in Central Thailand. This was achieved through comprehensive sampling and ITS rRNA gene sequencing, revealing associations and variations across different farming methods and locations..

## Results

Our findings demonstrated a diverse fungal community with a wide range of taxa, where the top 21 fungal families accounted for over 5% of the total reads. Notably, *Cladosporium*, *Aspergillus*, and *Fusarium* were identified, with *Cladosporium* being the most abundant across all samples. Additionally, differences in fungal abundance and diversity were observed between water and gill samples, with *Candida spp*. predominating in gill samples and *Rhodotorula spp*. prevailing in water samples. Canonical Correspondence Analysis (CCA) showed associations between fungal abundance and environmental variables. Alpha diversity analysis revealed significant differences between water and gill samples, with the sampling source exerting the greatest effect on fungal diversity. Furthermore, beta diversity analysis indicated substantial variations in fungal community composition across sampling locations and farming styles, underscoring the impact of environmental factors and aquaculture practices on fungal community dynamics.

## Conclusion

Overall, these findings offer valuable insights into the abundance, diversity, and distribution of fungal communities in red tilapia farms, emphasizing the need to consider fungal pathogens in aquaculture management strategies. Understanding the dynamics of these communities is crucial for mitigating disease risks, maintaining fish health, and ensuring food safety in aquaculture. Further research is necessary to clarify the specific mechanisms of fungal pathogenesis and the effects of environmental factors on fungal community dynamics in aquaculture settings.

# SEAWEEDS FED BLACK SOLDIER FLY LARVAE IN DIETS OF SMOLTIFYING ATLANTIC SALMON: EFFECTS ON THE INTESTINAL FLUID UPTAKE AND GROWTH PERFORMANCE

## Introduction

Marine aquaculture side-streams such as seaweeds are gaining increased attention as alternative aquafeed ingredients for fish relevent amino acid profile, presence of long-chain polyunsaturated fatty acids (PUFAs) and micronutrients. However, the complex carbohydrate structures in plant-based ingredients make them challenging to use directly in the diets of carnivorous species. Larvae of insects, as the black soldier fly larvae (BSFL) on the other hand, have emerged as promising candidates for convertion and valorization of different side streams and wastes into valuable feed ingredients. Particularly interesting are marine side-streams that have the potential to increase the PUFA and other nutritional values of the feed. Although some studies have explored the valorization of seaweeds through BSFL, salmon feeding trials incorporating algea derived BSFL are still scarse, particularly during sensitive developmental stages like the smoltification.

Atlantic salmon smoltification represent a critical life stage, when the fish undergo profound physiological changes to prepare for seawater (SW). A key adaptation during this transition is the developemnt of intestine and the fluid transport capacity which enables effective water absorption, a crucial osmoregulatory step in marine environments. Proper intestinal development during smoltification is therefore essential for successful seawater acclimation. To date, no studies have specifically investigated the impact of marine side-stream derived insect-based diets on intestinal fluid transport development and growth performance in Atlantic salmon during smoltification. Therefore, the main aim of the present study was to investigate how side-streams from seaweed farming, valorized through BSFL influence intestinal development in Atlantic salmon smolts with a particular focus on intestinal fluid transport capacity.

## Materials and methods

Atlantic salmon smolts were produced at the Lerang Research Station, Norway (Skretting Aquaculture Innovation), using a winter light regime (12 hours light:12 hours darkness, 12:12) for 6 weeks, followed by continuous light (24:0) at 12 °C. During the winter light period in freshwater (FW), triplicate groups of parr (~35 g) were assigned either a control diet or one of two insect meal diets: BSFL fed on Ulva (*Ulva fenestrata*) or BSFL fed on Kelp (*Saccharina latissima*). Insect meal diets (5% inclusion) were formulated to partially replace fishmeal in the control diet. The feeding trial was conducted for 12 weeks. Fish were then transferred to full-strength SW at 504 degree-days (dd). During the SW period, all fish were fed the same commercial diet for six weeks. Sampling was conducted in FW at 0 dd, 336 dd, and 504 dd as well as at the final sampling in SW at 1008 dd. At each sampling point, fish body weight (g) and intestinal mucosal weight (mg) were measured. Plasma was analyzed for ion concentrations, osmolality, and hormone levels (including IGF-1 and cortisol). Intestinal fluid transport rate was measured using the non-everted gut sac method, and $Na^+/K^+$-ATPase (NKA) enzyme activity using a kinetic enzyme assay. The intestinal nutrient transport capacity was also determined using Ussing chamber techniques.

*(Continued on next page)*

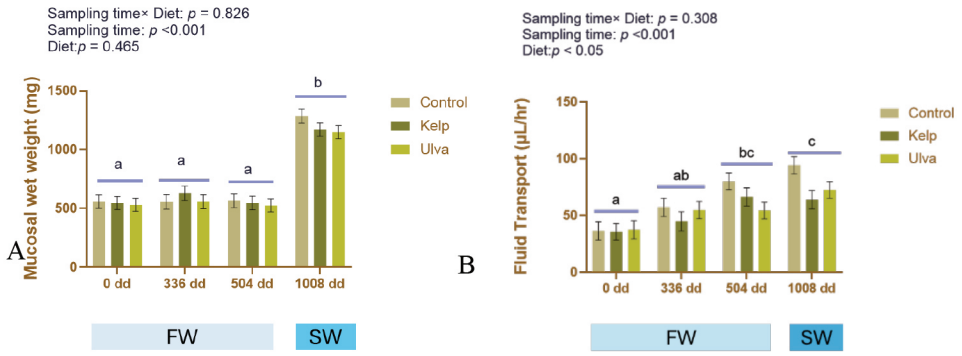

Figure 1: Intestinal mucosal mass (A) and fluid transport capacity (B). Lower case letters indicate the significant difference between sampling time ($p$ <0.05).

| | 0 dd | 504 dd | 1008 dd |
|---|---|---|---|
| Control | 76.18±1.28 | 110.57±1.60 | 145.82±2.00 |
| Kelp | 77.62±1.28 a | 112.63±1.57 b | 152.87±1.95 c |
| Ulva | 77.49±1.28 | 110.09±1.57 | 152.83±1.95 |

Table 1: Body weight (g) of Atlantic salmon parr to 6 weeks in SW
0 dd- Body weight (BW) of the parr, 504 dd- BW at the end of FW period and 1008 dd- BW at the end of SW period. Lower case letters indicate the significant difference between different sampling times ($p$ <0.05).

**Results**

Mucosal weight increased over time, with significantly higher mucosal mass observed in fish sampled after 6 weeks in SW at 1008 dd. No significant differences in mucosal mass were found between diets (Fig 1-A). Intestinal fluid transport capacity also increased over time with significantly higher values in SW fish. A general dietary effect was observed, where fish fed the control diet exhibited significantly higher intestinal fluid transport capacity compared to those fed BSFL meal based on kelp (Fig 1-B). Growth results showed that body weight increased by nearly 20% in the smolts at 504 dd compared to the parr at 0 dd. After six weeks in seawater (1008 dd) body weight increased by approximately 50% compared to the parr stage (Table 1). However, body weight was not significantly affected by different diets (Table 1).These findings suggest that BSFL-based diets supported similar growth performance to the control diet, with Ulva-based diet being the most promising candidate as fish fed the kelp-based BSFL diet showed lower intestinal fluid transport capacity. In-depth physiological results, including intestinal nutrient transport, barrier function, and NKA activity will be presented at the conference. Overall, these findings highlight both the potential and the challenges of using BSFL-valorized seaweeds diets to support intestinal development and seawater adaptation in Atlantic salmon smolts.

# AMPHIBIOUS TECHNOLOGIES FOR SUSTAINABLE AQUACULTURE: THE ROLE OF MAR (MULTIPURPOSE AMPHIBIOUS ROVER) IN COASTAL MONITORING, SAFETY, AND RESILIENCE

Eduardo De Francesco[1], Ruggero De Francesco[2]

The development of European aquaculture increasingly requires innovative technologies that can support environmental sustainability, operational safety, and social acceptance of production activities.

In this context, the MAR – Multipurpose Amphibious Rover (www.eco-mar.it) represents an advanced and versatile solution for operations in complex coastal environments such as lagoons, estuaries, and intertidal zones—areas that are often beyond the reach of traditional automation and control systems.

Designed to move across land, mud, and shallow water, MAR is a modular, fully electric amphibious mobile platform developed for civil, environmental, and infrastructure protection applications.

Its integration into the aquaculture sector opens new opportunities for smart management of farms and continuous ecosystem monitoring.

This contribution explores the potential applications of MAR in support of sustainable aquaculture, with specific reference to the coastal context of Valencia and other Mediterranean regions:

- Real-time environmental monitoring using onboard sensors (water quality, turbidity, microplastics, etc.);
- Surveillance and protection of aquaculture infrastructure against natural damage or unauthorized access;
- Low-impact logistical support for inspection and maintenance of cages, rafts, and piers;
- Technical training and outreach, offering a mobile and interactive platform for education and stakeholder engagement.

MAR contributes to the Blue Economy paradigm and aligns with the goals of the European Green Deal, offering a concrete solution to drive a digital and green transition in the aquaculture sector. Its adoption can strengthen engagement with local communities, increase transparency, and improve the public perception of aquaculture as a sector compatible with environmental integrity and socio-economic development.

The presentation aims at the creation of collaborative pathways with academic institutions and local producers, laying the groundwork for integrated pilot projects in the Mediterranean region.

# FEEDING IMMUNITY: EVALUATING FUNCTIONAL DIET EFFECTS IN RAINBOW TROUT (*Oncorhynchus mykiss*) DURING AN *A. salmonicida* OUTBREAK

Teresina De Iorio[a*], Maria Carmela Scatà[a], Francesca Apuzzo[b], Alessandra Crisà[a], Andrea Gustinelli[b], Cinzia Marchitelli[a], Arianna Martini[a], Marco Martinoli[a], Riccardo Napolitano[a], Domitilla Pulcini[a], Nicolò Tonachella[a], Fabrizio Capoccioni[a]

**Introduction**

The misuse or overuse of antibiotics has caused the onset of antimicrobial-resistant strains of *Aeromonas salmonicida* in fish and the aquatic environment. Different strategies have been proposed to boost fish resistance to *A. salmonicida,* one of the major pathogens of salmonids. Among the preventive approaches explored to increase natural resistance to disease in fish, probiotics, prebiotics, and immunostimulants have emerged (Minářová et al. 2021).

This study conceived an integrated approach to explore the potential immunomodulatory effects of a commercial feed, Protec (Skretting), which contains β-glucans, vitamins C and E, and zinc (Bulfon et al., 2019), and its ability to mitigate the mortality caused by a naturally occurring *A. salmonicida* outbreak in adult rainbow trout.

**Materials and Methods**

Adult rainbow trout (~300 g) were farmed in central Italy (Granica, RI). The animals were fed once a day with two commercial pelleted diets: 1) Optiline (Optiline, Skretting), used as a control diet, and 2) Protec (Protec, Skretting). Shortly after starting the commercial feeding trial, the farmer noticed a steady low-level mortality in both groups. After three weeks, 25 Optiline and 33 Protec fish were randomly caught using a fishing wade and immediately sacrificed for further examinations, as follows. External welfare indicators (Noble et al., 2022), biometric and autoptic indices were recorded. Peripheral blood was collected from the caudal vein and immediately transferred to heparinized tubes. The etiologic agent of the outbreak was detected by inoculating Tryptone Soy Agar (TSA) and Blood Agar (BA) plates with target organs (brain, kidney, and spleen). Identification of the isolates was performed phenotypically by MALDI-TOF (MALDI Biotyper, Bruker), while the subspecies was genotypically identified by INgene® q *Aeromonas salmonicida* (Gold Standard Diagnostics) through the StepOne Plus (Applied Biosystems). Blood cell count was assessed at 400X magnification under an Axioplan microscope (Zeiss), and innate immunity parameters (leukocyte viability, Reactive Oxygen Species (ROS) production, and phagocytosis activity) were evaluated by flow cytometry with the CytoFLEX instrument (Beckman Coulter) and analysed with Kaluza software v 2.1 (Beckman Coulter).

Cell counts were analysed using the Chi-square test, while the other parameters were tested using the non-parametric Mann-Whitney (Bonferroni-corrected $p$-value; $p < 0.05$ was considered significant). Statistical analysis was performed with the open-source software Past v. 4.14.

**Result and discussion**

After three weeks of the commercial feeding trial, no differences in either external welfare indicators or biometric parameters were observed between the Optiline and Protec groups. However, both groups showed Hepato-Somatic Index (HSI) and Spleen Somatic Index (SSI) values nearly twice the optimal range for rainbow trout (Nabi et al. 2022; Cardinaletti et al. 2022), suggesting that the mortality recorded could be related to the presence of an infectious agent. Mortality was significantly higher in the Optiline group compared to Protec ($p<0.001$), suggesting an improved immune competence in trout fed with an immunostimulant-rich diet (Redivo et al. 2023).

*(Continued on next page)*

The bacteriological culture examination of the target organs revealed the presence of systemic *A. salmonicida.* The subspecies *salmonicida* was detected in blood samples with no statistical differences in prevalence (28% Optiline *vs.* 21% Protec). However, the Optiline group displayed a significantly higher *A. salmonicida* gene copy number compared to the Protec group ($p<0.05$), suggesting a less efficient pathogen clearance in individuals fed with the Optiline diet. Consistently, trout fed with Protec showed a higher proportion of blood lymphocytes ($p<0.05$) and thrombocytes ($p<0.05$), and a lower number of neutrophils ($p<0.05$). Lymphocytosis has been related to greater recruitment and activation of specific immune cells during systemic defensive response against bacteria (Bulfon et al., 2019). Furthermore, a significantly lower number of leukocyte aggregates (leucoagglutination) was detected in the Protec group compared to the Optiline ($p<0.01$).

Leukocytes isolated from trout fed with Protec showed significantly higher viability ($p<0.01$), and lower apoptosis and death ($p<0.05$), paralleled by lower ROS production ($p<0.05$). They also exhibited a greater proportion of phagocytic ROS-producing live myeloid cells ($p<0.05$). Overall, these data suggested that the immunostimulants included may induce a greater pathogen clearance in trout leukocytes (Dalmo and Bøgwald 2008).

**Conclusion**

Although severe alterations have occurred in fish affected by the pathogen, regardless of the diet administered, the data obtained by the conceived integrated approach suggest that the immunostimulant-enriched diet strengthens rainbow trout's immune systems, partially mitigating *A. salmonicida* infection.

## Introduction

Climate change brings a significant challenge to aquaculture systems, especially in cage farming where rising water temperatures can negatively affect fish health and performance. Increasing water temperatures over the past decades have been reported for the Mediterranean Sea (Pastor et al., 2020), inland waters like the Black Sea in Turkey (Sakalli & Başusta, 2018), and lakes and rivers in Italy (Gavioli et al., 2024). Global warming is not expected to halt in the near future and will increasingly affect aquaculture. In rainbow trout (*Oncorhynchus mykiss*), heat stress can impair immune function and gut health, and reduce nutrient digestibility. The associated decline in performance poses a challenge for the productivity in aquaculture systems. With the dietary supplementation of a nutritional emulsifier based on polyethylene glycol ricinoleate (PEGR), an improved digestion, particularly of fats and oils, can be obtained. Moreover, our previous research already demonstrated microbiota shifts due to extreme heat in farmed gilthead sea bream were partially reversed by nutritional intervention with PEGR (Domingo-Breton et al., 2024). This study, evaluated the potential of a PEGR-based nutritional emulsifier to mitigate the effects of heat stress in rainbow trout.

## Material and Methods

A 12-week feeding study was conducted at the trial facilities of ABT Innovia in Malta with a total of 600 rainbow trout (initial weight 111.77g). Fish were randomly assigned to twelve tanks across four dietary treatment groups: Control, 750 ppm PEGR-based nutritional emulsifier (Volamel Extra produced by Nukamel BV, the Netherlands - 750V), 1000 ppm nutritional emulsifier (1000V) and 1250 ppm nutritional emulsifier (1250V). Fish were fed their respective experimental feeds as 4.5 mm pellets three times daily, at a fixed rate based on body size. Water temperature was maintained at 16 ± 2°C during the first eight weeks of the trial, and then gradually increased by 1°C per day to a final temperature of 22 ± 2°C to induce heat stress. Growth performance and health parameters were monitored and statistically analyzed with ANOVA, using post-hoc multiple comparisons with Tukey HSD test.

## Results

No significant differences between treatments were observed in the thermoneutral phase during the first eight weeks (Figure 1).

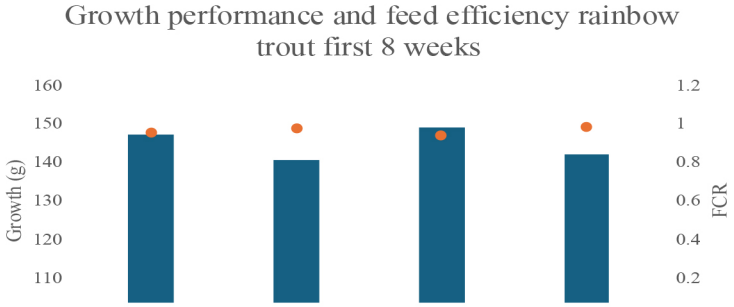

Figure 1: Growth performance and feed efficiency of rainbow trout fed diets with different levels of a PEGR-based nutritional emulsifier in thermoneutral condition

*(Continued on next page)*

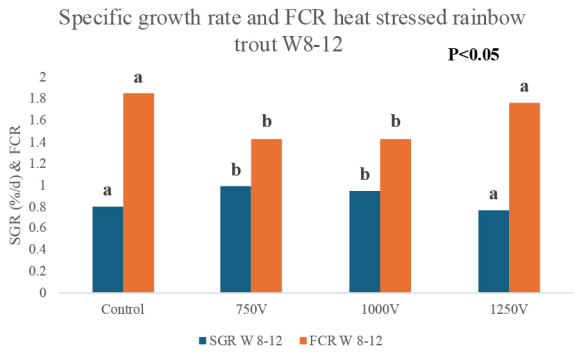

Figure 2: Specific growth rate and FCR of rainbow trout under heat stress from week 8 to week 12.

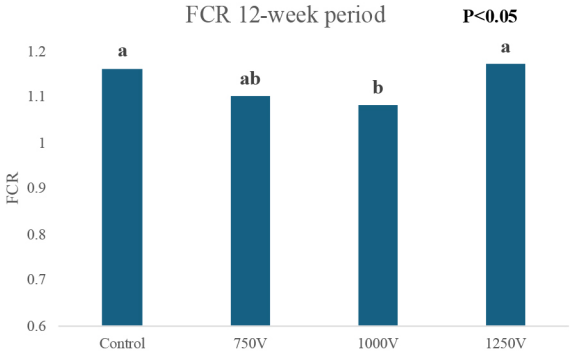

Figure 3: FCR rainbow trout fed different levels of emulsifiers over a 12week period

Under heat stress, both treatments with nutritional emulsifier (750V and 1000V) showed significantly higher growth and lower FCR compared to control (Figure 2). Survival was numerically better, while hepatosomatic index (HSI), and viscerosomatic index (VSI) showed a significant increase in the diets with the nutritional emulsifier.

For the overall 12 weeks trial period, 1000 ppm of nutritional emulsifier showed a significant improvement in the FCR ($p<0.05$) and a trend towards higher growth ($p=0.1$). Survival and K-factor (condition factor) were unaffected across treatments.

**Discussion**

During heat stress a lot of changes in metabolism take place and can be accompanied by changed levels of HSI and VSI and can be harmful for fish health. A decrease in performance is often recorded, resulting in production losses for aquaculture systems. Nutritional emulsifiers based on PEGR can influence the gut dynamics of carnivore fish. This trial showed that addition of a nutritional emulsifier can mitigate the negative effects on growth performance and feed efficiency of carnivore fish under heat stress challenge. More research is needed to see the effect on other mechanisms in the fish, such as digestibility, immunity and antioxidant capacity.

**Conclusion**

Inclusion of a nutritional emulsifier based on PEGR helped maintain growth and feed efficiency under heat stress conditions in rainbow trout. This suggests that such emulsifiers can be a valuable nutritional strategy to improve resilience in aquaculture systems facing rinsing temperatures and heat stress, maintaining production to reasonable levels.

# IMPLEMENTING THE STRATEGIC GUIDELINES FOR EU AQUACULTURE: EUROPEAN COMMISSION STAFF WORKING DOCUMENTS ON PLANNING OF SPACE AND ACCESS TO WATER FOR MARINE AQUACULTURE AND ACCESS TO SPACE AND WATER FOR FRESHWATER AND LAND-BASED AQUACULTURE

L. De La Cruz-Iglesias[1], E. Gargallo-Gonzalez[1], A. Lane[2],T. Pacchiarini[3], P. Xandri[3]

[1]European Commission, DG Maritime Affairs and Fisheries, Unit A2 – Blue Economy Sectors, Aquaculture and Maritime Spatial Planning, 1049 Brussels, Belgium
[2]European Aquaculture Society, Otterburcht, Ottergemsesteenweg Zuid 713, 9000 Gent, Belgium
[3]NTTData, Camino de Fuente la Mora, 1, 28050 Madrid, Spain.

The Commission Staff Working Documents (SWDs), on "Planning of space and access to water for marine aquaculture"[1] and "Access to space and water for freshwater and land-based Aquaculture"[2], serve as complementary resources aimed at implementing the "Strategic Guidelines for a more sustainable and competitive EU aquaculture for the period 2021 to 2030"[3]. Together, the two SWDs, provide comprehensive guidance for authorities and policymakers in Member States (MSs), addressing the allocation of space and access to water for both marine and freshwater aquaculture activities.

The SWDs were produced by the European Commission in collaboration with the Aquaculture Assistance Mechanism[4] (AAM) employing a thorough methodology to select good practices from EU and non-EU countries on the topic access to space and water. The methodology includes desk research and tools, such as: surveys, technical seminars, a workshop held in Brussels in 2023, and several online interviews with European aquaculture experts. Recently, e-learning modules were produced by the AAM on both documents to boost the good practices exchange among MSs.

The SWD on "Planning of space and access to water for marine aquaculture" explains social, economic, environmental, and regulatory conditions of the EU marine aquaculture sector, and identifies key challenges faced by public authorities with competencies in marine aquaculture spatial planning.

Similarly, the SWD on "Access to space and water for freshwater and land-based aquaculture", addresses: lack of social acceptance, conflicts with other activities, cost of space, water rights and licenses, application of the Water Frame Directive (WFD) and River Basine Management Plans (RBMPs) which, among others challenges, are factors that are restraining the competitiveness and further development of the freshwater and land-based aquaculture sector in the EU.

Both SWDs outline the necessary steps for effective access to space and water for all types of aquaculture and consolidate existing good practices and tools. The factsheets included in the SWDs address solutions to the identified challenges and provide practical example from both EU and non-EU countries. The factsheets, which emphasise the benefits of the selected good practices, also provide guidance to EU public authorities on how to implement such solutions, to enhance the planning processes, and ensuring sustainable aquaculture development in the European Union.

4. The AAM is part of a Service Contract jointly managed by the European Climate, Infrastructure and Environment Executive Agency (CINEA) and DG MARE. The consortium is coordinated by NTT DATA, Poseidon, SCOPE - Netcompany, the European Aquaculture Society (EAS) and the European Aquaculture Technology and Innovation Platform (EATIP). https://aquaculture.ec.europa.eu/

# PRELIMINARY DATA ON STRESS BIOMARKERS IN *Anemonia sulcata*

E. de la Roca*, J.F. Ferrer, N. Salamanca, M. Herrera.

IFAPA Centro 'Agua del Pino'
Punta Umbría - El Rompido rd. 21459
Cartaya, Spain
Email: melena.roca@juntadeandalucia.es

## Introduction

The sea anemone *Anemonia sulcata* is considered a highly valuable species in Andalusia (Spain) and, consequently, its wild stocks are significantly decreasing due to overfishing. The culture of this species could contribute to mitigate the fishing pressure and promote the restoration and long-term conservation of *Anemonia sulcata* populations. Nevertheless, there is a lack of information about its physiology and behaviour, necessary for optimizing culture conditions.

To enhance the health, growth, welfare, and productivity of cultured species, it is essential to identify and minimize potential stressors. Understanding the physiological status of the animals is crucial for determining the presence and severity of stress. This assessment is commonly performed through the analysis of stress-related biomarkers, including metabolites linked to physiological responses (e.g., lactate, glucose, cortisol) and the activity of antioxidant enzymes (e.g., superoxide dismutase, catalase, glutathione peroxidase).

The aim of this study was to assess whether specific stress-related metabolites and antioxidant enzyme activities could be detected in *Anemonia sulcata* following exposure to various acute and chronic stress conditions.

## Materials and methods

Anemones were collected from 3-4 m depth at La Herradura beach (Granada), and afterwards acclimated in highly-aerated seawater tanks at IFAPA Centro "Agua del Pino" (Cartaya, Huelva). For this study 39 anemones (mean wet weight 25.11 ± 3.57 g) were randomly placed into 9 circular tanks exposed to natural temperature and light cycles. They were fed three times a week with commercial fish feed (pellets). The experiment was started after an acclimation week. 12 anemones were assigned to each of the three treatments: control (CTRL), normal culture conditions; Acute stress (A), animals exposed for six hours to a desiccation period outside the cultivation tank; **Chronic stress (C),** animals kept in darkness and starvation for 10 days. Each treatment was performed in triplicate. The experiment period lasted 45 days. At the end of the trial, pedal tissue samples were collected to analyze stress-related metabolites (lactate and glucose) and the activity of antioxidant enzymes such as glutathione peroxidase (GPx) and superoxide dismutase (SOD).

## Results and Discussion

An independent samples Student's *t*-test was conducted to detect significant differences between treatments for glucose and lactate levels and GPx and SOD activity. Statistically significant differences were detected for all biomarkers (Table 1).

**Table 1.** Glucose and lactate concentrations, and glutathione peroxidase (GPx) and superoxide dismutase (SOD) activities in control (CTRL) anemones and those exposed to acute stress (A) and chronic stress (C). Mean ± SE values for every biomarker and treatment. Asterisks indicate significant differences regards the control group.

| | TREATMENTS | | |
|---|---|---|---|
| BIOMARKER | CTRL | A | C |
| GLUCOSE (mg/g) | 0.21±0.12 | 0.70±0.23 * | 0.50±0.14 * |
| LACTATE (mg/g) | 0.09±0.03 | 0.19±0.05 * | 0.11±0.05 |
| GPx (U/g of protein) | 0.18±0.06 | 0.23±0.03 * | 0.12±0.06 |
| SOD (U/g of protein) | 7.30±4.88 | 1.64±2.24 * | 1.00±0.70 * |

*(Continued on next page)*

These findings indicate that stress in sea anemones induced a metabolic and antioxidant response. Elevated glucose levels were observed in both acute and chronic stress conditions, likely to facilitate rapid mobilization of energy reserves during stress exposure. Regarding lactate, anaerobic metabolism was detected under acute stress, characteristic of hypoxic conditions; however, no significant differences were found during prolonged stress, suggesting an adaptive adjustment of basal metabolism by the anemones over time. In terms of the antioxidant response, GPx activity was upregulated in response to increased reactive oxygen species (ROS) during acute stress, whereas chronic stress led to a decrease in GPx activity, although this reduction did not reach statistical significance, potentially indicating depletion of antioxidant reserves. Lastly, the marked reduction in SOD activity observed under both acute and chronic stress suggests a compromised antioxidant defense system, with the effect being particularly pronounced under chronic stress conditions.

**Conclusion**

The stress-related biomarkers lactate, glucose, GPx activity, and SOD activity were detected in *Anemonia sulcata* following exposure to stress conditions, suggesting their suitability as reliable indicators of welfare status in the culture of this species. Further studies will be necessary to test other stress markers commonly used in aquaculture.

## Introduction

Pediatric cancer is the leading cause of childhood death in Spain. The severity of this disease causes Post-Traumatic Stress Disorder (PTSD) mainly in parents. Previous studies (López, 2019) agree on the importance of generating positive stimuli that produce Post-Traumatic Growth (PTG). This is where the European Project IGNITION acts as a link by studying the improvement of welfare and health in aquaculture. In this context, the training action will show children, during and after a PTSD process, the world of aquaculture, giving the opportunity to learn with their families its functioning to extrapolate it to their own medical circumstances. This will have special emphasis on the interrelationship of fish and healthy eating with human and environmental welfare ("One Health concept"), generating a positive action that directly brings science closer to children and their families. Through the use of different game dynamics, they will discover the similarity between the medical tests performed on them during their treatments and the tests we conduct to assess the health status of our farmed fish. By using positive actions like these, childrens were able to forget where they were and lose some of their fear of certain tests they undergo, such as a simple blood draw.

## Materials and methods

The activities were carried out at Hospital Puerta del Mar in Cádiz and Hospital Universitario de Jerez, once a week each for a period of 2 months. The target audience was children aged 4-14 years who were hospitalized for various pathologies or who attended the hospital for oncological treatment. The total number of people who participated in the workshops was around 100, including children and their families. Throughout the period in which the workshops were held, various activities were implemented with the aim of bringing scientific knowledge of aquaculture closer to hospitalized children and their families with a playful approach adapted to the different ages of the attending public. All activities had a dynamic, playful, and easy-to-understand basis for the target audience, even creating didactic prototypes to bring and introduce the aquaculture world in such a different environment as a hospital.

During the workshops, 4 types of activities were carried out:

1. "Unsustainable Jenga" game to demonstrate the fragility of marine ecosystems.
2. Experiment on varied and healthy eating (fish as part of it) vs. processed foods.
3. Visualization of aquaculture species used for human feeding.
4. Scientists for a day: simulation of an aquaculture sampling.

**Figure 1**. Images during and after the completion of the workshop in the playroom of the Hospital Puerta del Mar de Cádiz and Hospital Universitario de Jerez. Own elaboration.

*(Continued on next page)*

At the end of the workshop, the children became little researchers for a day, learning about our work as researchers and how our work is focused on obtaining more sustainable diets in aquaculture, ensuring and guaranteeing animal welfare. In order to bring the aquaculture world closer in a realistic way, and given the impossibility of handling live animals in a hospital environment, an alternative was sought through the use of stuffed fish, allowing children to identify and touch aquaculture species, and draw blood from them in the same way researchers done to check animal welfare. The development of a didactic prototype for blood extraction simulation and video projection reinforced the set of activities, connecting them with scientific reality, which was highly valued by the adult audience.

**Results and discussion**

These sessions allowed participants to explore the complex aquatic ecosystem, understand the importance of sustainability in marine resource management, and the importance of aquaculture and science in all of this, with aquaculture being the central axis of all activities as a sustainable alternative for marine protein production in the growing global food supply. Although the hospitalized children presented various pathologies and moods, both the type of activities and the topic addressed managed to connect with each of them and enthuse them, making their participation very active. With the general objective of bringing science closer to children undergoing oncological treatment and their families, and promoting the consumption of aquaculture fish as a healthy and sustainable option through outreach activities and simple experiments, children learned to distinguish healthy foods from processed products, while adults discovered the nutritional and environmental benefits of aquaculture as a safe and balanced food source.

During the period the workshop lasted, both children and adults became researchers, transforming hospital playrooms into small laboratories, an activity always focused on seeing the similarity with medicine and their hospital status.

**Conclusions**

Our work demonstrates a different approach to aquaculture outreach, bringing this world to an unusual environment. These activities not only allow participants to disconnect from their surroundings but also discover a world unknown to most of them, such as aquaculture. Through communication mainly with the adult audience, we discovered that it remains a little-known sector, which shows the need to continue and emphasize closer and more effective communication. Likewise, the healthcare staff showed their interest in carrying out such uncommon workshops in the hospital playrooms (while waiting for oncological treatments) for understanding the significance healthy eating with the consumption of fish in the diet. These areas are a good place for learning as long as the objective of these rooms is not lost. Thanks to the feedback we received from the participants, it has been one of the most enriching experiences for all those who participated in this project, as conveyed by the families involved.

## Introduction

In recent decades, Spain has become one of the main aquaculture producers in Europe. However, aquaculture remains largely unknown and undervalued by part of society, reflecting a limited understanding of the scientific research aimed at promoting its sustainable development. This disconnect also influences consumer perception and acceptance of aquaculture products, which are sometimes viewed with skepticism despite their high quality and environmental benefits. Moreover, despite the Spanish education law (LOMLOE 3/2020) integrating the Sustainable Development Goals (SDGs), sustainable aquaculture, intrinsically linked to several SDGs (1, 2, 8, 12, 14), is not a topic considered for working on the SDGs. Working on the SDGs from an early age becomes important to achieve this issue (Cernev and Fenner, 2020). It is therefore crucial to disseminate the advances of this sector beyond the scientific realm to mitigate the social stigmatization derived from a lack of understanding. Bringing these concepts closer to future generations is fundamental for effective knowledge transfer that fosters a positive connection between science, aquaculture, and society, aligning actions within the 2030 Agenda: 'Think globally, act locally to achieve change'.

## Materials and methods

This study was conducted with the aim of bringing the aquaculture world closer to primary students. Through an active methodology, activities and audiovisual materials, it highlighted the value of farmed fish and its research thanks to the correlation between: i) fish as an important source of omega 3, ii) the importance of stablishing good nutrition in cultivated fish larvae with sustainable raw materials, and iii) the respect for the marine environment. These activities were carried out in two Primary Schools in Spain, one located in the Bay of Cádiz with a culture close to the sea (C.I.E.P Arquitecto Leoz), and the other located in Madrid, without such marine connection (Colegio Aquila). The workshops were carried out over two consecutive days and involved a total of 433 students, aged between 9 and 13 years. Before starting the activities, a concept test composed by 4 simple questions was administered to all students using a game called "Port and starboard" to be answered with either "Yes" or "No":

***Q1:*** Do you like to eat fish?
***Q2:*** Is the origin of all fish that we consume from extractive fishing?
***Q3:*** Do you know what overfishing is?
***Q4:*** Do you know what aquaculture is?

After the initial test, and considering its results, various practical and visual activities were carried out. These interventions were addressed to introducing concepts and knowledge that the students lacked, in order to gain a significant understanding of aquaculture and scientists' advances, making it more sustainable.

## Results and discussion

From the 433 primary students, 55.4% (n=240, within both locations) were from the 4$^{th}$-grade, 22.2% (n=96) from 5$^{th}$-grade, and 22.4% (n=97) from 6$^{th}$-grade. After analyzing the results, 75.5% of the students like to eat fish, and 81.1% considered that all the fish they consume come from extractive fishing. However, 67.4% did not know the meaning of overfishing, and 94% did not know what aquaculture is. These results also remark a clear age-dependent factor mainly related to both Q2 and Q3 questions, but not in the case of Q4.

*(Continued on next page)*

Likewise, within the totality of 4th-grade primary students, two groups were differentiated according to their living area, either near the coast (Cádiz, 40.4%) or inland on the Iberian Peninsula (Madrid, 59.6%). Focusing on these sub-groups, the results showed that, regarding question Q1, 81.4% of coastal students like to eat fish, compared to 72% of inland students. Moreover, answers to Q2 show that 94.8% (Cádiz) and 96.5% (Madrid) of students consider that fish they consume come from extractive fishing. Besides, only 13.4% of coastal students knew the term overfishing (Q3) and 3.1% the term aquaculture (Q4) compared to 7% and 2.8%, respectively, of the students living inland on the Iberian Peninsula.

These results show that most primary students believe that the fish they consume comes from extractive fishing and, therefore, the term of aquaculture is completely unknown to them. This hiaghlights that 4th grade of primary school is the educational moment when students begin to work more autonomously (Casado Berrocal and Castro Bayón, 2017), being an ideal stage to acquire the knowledge and habits that allow them to use the environment sustainably, becoming future agents of change (Ruiz et al., 2025).

Implementing the concepts of sustainable aquaculture within educational programs through gamification and collaborative learning as a methodological approach will enable students to receive an education in future consumption from an ecological and sustainable perspective (Torralba Burrial and Dopico Rodríguez, 2021). Furthermore, the introduction of innovative and playful activities in education, as has been the case, is a recognized phenomenon to support the learning process (Makri et al., 2021).

**Conclusions**

The presentation of these results through the use of creating specific activities for this purpose generates a positive connection between science, aquaculture and society, cultivating interest from an early age. It is important that these messages with the audience do it, although a "bottom-up" knowledge transfer design is needed to ensure complete assimilation at more complex levels. Despite Spain's deep relationship with the sea and its products, educational curricula tend to prioritize terrestrial agriculture, revealing a notable absence in the teaching of aquatic cultivation.

# MICROBIOME PROFILING OF SUBMARINE WASTEWATER OUTFALLS FOR COASTAL WATER QUALITY MONITORING IN THE GULF OF VALENCIA

Ana de Luis-Margarit*[1], Alejandro Suay[1] and David Talens-Perales[1,2]

(1) IMEDMAR-UCV Universidad Católica de Valencia. C/ Guillem de Castro 94, 46001 Valencia, Spain
(2) Instituto de Agroquímica y Tecnología de Alimentos, Consejo Superior de Investigaciones Científicas (IATA-CSIC), 46980 Paterna, Valencia, Spain
* Presenting and corresponding author: ana.deluis@ucv.es

## Introduction

The Valencia metropolitan area, positioned along the Gulf of Valencia, confronts major pollution issues from urban and industrial discharges. Effective monitoring of water quality is critical, but traditional methods relying on physical-chemical and microbiological analyses are time-consuming and require skilled personnel, making them impractical for large-scale monitoring. In this preliminary study, we perform a year-round microbiome composition assessment of the water column from several discharge points from selected submarine outfalls linked to wastewater treatment plants, with the aim of detecting seasonal biomarkers for an enhanced monitoring of coastal water quality.

## Methodology

Samples were collected in three replicates from four distinct submarine outfall discharge points and two farther points controls, across all four seasons of the year. Water sampling (5L) was conducted aboard the IMEDMAR-UCV research vessel using a peristaltic pump, collected at 1 meter depth and filtered through 0.45 μm MCE sterile filters. DNA was extracted using a proprietary protocol (unpublished). DNA libraries were constructed through the amplification of prokaryotic 16S rDNA (Caporaso et al. 2012) and sequenced using the Illumina® technology. DNA sequences were analyzed with MOTHUR and statistical analyses were performed using RStudio and tools from different packages such as DESeq2, Microeco, Vegan and FAPROTAX.

## Results

The comparative analysis performed with *Linear Models for Differential Abundance (LinDA)* (Figure 1A) showed significant differences in the relative abundance of several bacterial taxa between the control site and the submarine outfall points. The latter showed a marked increase in *Sulfurimonas*, *Fusibacter*, *Candidatus Peribacteria*, *B2M28*, *Candidatus Komeilibacteria*, Peptostreptococcales–Tissierellales, and *Desulfosarcinaceae*, all with statistically significant differences ($p < 0.05$). In contrast, other groups such as *Bdellovibrio* and *Pir4 lineage* showed no relevant changes between conditions. Functional inference of metabolic functions using FAPROTAX (Figure 1B) showed that most processes displayed similar relative abundances in outfall and control sites, except for pathways related to the respiration of sulfate and sulfur compounds, which were significantly higher in the outfall samples, whereas the control sites exhibited comparatively higher values for other oxidation and methylotrophy pathways.

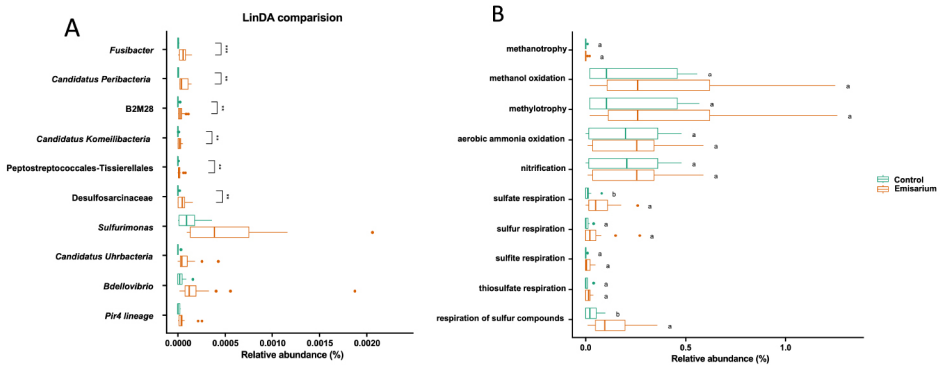

Figure 1. (A) Differential abundance analysis performed with LinDA comparing microbial communities between the control and outfall (*Emisarium*) sites. (B) Functional profiling of metabolic pathways showing significant differences between sites based on FAPROTAX annotation.

*(Continued on next page)*

**Discussion**

Our data revealed significant shifts in the microbial community composition between the control and submarine outfall sites, indicative of environmental impacts associated with the outfall discharges. The notable enrichment of taxa such as *Sulfurimonas* or *Desulfosarcinaceae*, among others, in the outfall samples suggests a selection for microorganisms adapted to sulfur-rich or reducing conditions, such as seen in other studies linked to polluted marine environments (Zhang et al., 2007; Chen et al., 2019). Furthermore, functional inference underscored these taxonomic shifts, confirming a biogeochemical alteration toward a sulfate and sulfur-driven microbial ecosystem, possibly derived from a more anaerobic and sulfur-rich environments on these sites.

**Conclusions**

Overall, these results highlight the influence of wastewater submarine outfall discharges on microbial community structure and function, favoring sulfur-metabolizing bacteria and altering biogeochemical cycles.

# ASSESSING THE IMPACT OF CLIMATE CHANGE - DRIVEN ACIDIFICATION IN THE ADRIATIC SEA ON BYSSUS PRODUCTION, BEHAVIOUR, AND SHELL BIOMINERALIZATION IN *Mytilus galloprovincialis*

A. De Marco*[a], D. Nordio[a], D. Montroni[b], G. Falini[b], L. Mandrioli[a], A. Bonaldo[a]

[a] Department of Veterinary Medical Sciences, University of Bologna, Bologna, Italy
[b] Department of Chemistry, University of Bologna, Bologna, Italy
*Contact E-mail: antonina.demarco@unibo.it

**Introduction**
The increase in atmospheric $CO_2$ levels is causing a progressive acidification of sea water. Projections indicate a decrease in ocean surface pH by approximately 0.3–0.5 units by the year 2100. This future condition could affect calcifying marine organisms, particularly bivalves, due to their reliance on carbonate ions for shell formation. *Mytilus galloprovincialis*, the Mediterranean mussel, is both ecologically important and economically valuable in European aquaculture. This study aims to investigate how predicted acidification scenarios may influence mussel byssus production, gregarious behaviour, shell integrity, and molecular responses related to calcification.

**Materials and Methods**
*M. galloprovincialis* (n = 288; shell length 3.5 ± 0.5 mm) were collected from a commercial mussel farm in the North Adriatic Sea and acclimatized in controlled laboratory aquaria. The mussels were then randomly assigned to four experimental pH treatments (8.2 – control, 7.9, 7.7, and 7.4), simulating current and predicted future ocean conditions based on IPCC projections. pH was modulated and stabilized using $CO_2$ bubbling systems over a 90-day exposure period. Total alkalinity was measured weekly to determine carbonate system parameters, including aragonite and calcite saturation state.

Byssus thread production was assessed at multiple intervals (1, 3, 6, 9, 12, 18, and 24 hours). Mussel positions were recorded on a grid at the bottom of aquaria, to quantify clumping events in aggregation behaviour and crawling speed (mm/h).

Shell quality was evaluated through scanning electron microscopy (SEM), mechanical strength testing under pressure, and mineralogical analysis via X-ray diffraction.

Histological analyses of mantle tissue were conducted using Alizarin Red S staining to localize calcium deposits useful for shell formation.

Furthermore, expression levels of key genes associated with biomineralization (chitin synthase, calponin-like protein, carbonic anhydrase, tyrosinase 1–2, chinase, plasma membrane $Ca^{2+}$ ATPase and sarcoplasmatic $Ca^{2+}$-binding protein) were quantified using RT-qPCR on outer and inner mantle tissue samples.

**Results and Discussion**
No significant decrease in byssus production was observed between pH treatments, only an increase over time (Fig.1). But behavioural alterations emerged such as decreased clumping (Fig.2) and mobility under low pH conditions. Mussels exposed to acidified seawater compromised shell ultrastructure and mechanical properties, with altered mineral phase composition. At the tissue level, a redistribution of calcium within the mantle parts was observed, suggesting disruptions in shell formation processes. Gene expression analyses revealed downregulation of biomineralization-related genes under low pH, indicating impaired physiological regulation of shell formation.

**Conclusion**
This study provides a comprehensive assessment of the effects of ocean acidification on *M. galloprovincialis*, integrating behavioural, morphological, and molecular endpoints, it highlights the species' sensitivity to low seawater pH, with implications for mussel productivity under future climate scenarios.

*(Continued on next page)*

# MICROBIOTA OF *Manila clam* SPAT PRE-FATTENED IN DIFFERENT FARMING TECHNOLOGIES

A. De Marco*[a], L. Aguiari[c], E. Scarpa[c], E. Benini[a], A. Bonaldo[a]

[a] Department of Veterinary Medical Sciences, University of Bologna, Bologna, Italy
[c] NaturEdulis s.r.l. hatchery, Goro, Ferrara, Italy
*Contact E-mail: antonina.demarco@unibo.it

**Introduction**
Microbiota plays a critical role in bivalve health and resilience. Farming systems for Manila clam could optimize growth and influence the associated microbiota, which also depends on environmental conditions. This study aimed to compare three pre-fattening supports by evaluating the growth performance and composition of the clam microbial communities.

**Materials and Methods**
Three different pre-fattening systems were tested at NaturEdulis (Goro, Italy) for four months: net lanterns suspended in superficial sea water; poches in less superficial water, land-based upwelling tanks within the hatchery. Spat (4.68±0.53 mm in length) were monitored monthly. Six clams per group were sacrificed to measure growth parameters and to characterize the microbiota (alpha and beta diversity, microbiota composition at phylum level). At monthly sampling, microbial DNA was extracted using the DNeasy PowerSoil kit (Qiagen, Hilden, Germany), and the V3–V4 hypervariable region of the 16S rRNA gene was amplified via PCR for high-throughput sequencing.

**Results and Discussion**
Clam growth was evident in all systems, with significant increases in length and total weight over time, particularly in the lantern support. This trend followed the Chl a concentration, which was generally higher in the lantern environment.

The microbial community composition of clams varied significantly across sampling times and support types. At T0, *Pseudomonadota* dominated, while *Bacillota* became more prevalent in later samples, with *Cyanobacteriota* dominating from June. In the final sampling, *Spirochaetota* and *Chloroflexota* were predominant in the poche support. Diversity increased over time, with T0 showing the lowest diversity.

**Conclusion**
The lantern support was identified as the most effective pre-fattening system, promoting superior growth performance. Microbiota shifts suggest that environmental factors and support type play a key role in shaping microbial communities. The poche system appeared to be the least efficient, likely due to mesh fouling, which reduced both water flow and microbial diversity.

**Funding**
This research was undertaken under the BIVALVI (ERA-NET BlueBio: Advancing European bivalve production systems) project, which has received funding from the European Union's Horizon2020 Research and Innovation programme under grant agreement no. 817992 (https://bluebioeconomy.eu/advancing-european-bivalve-production-systems/)

*(Continued on next page)*

# COMPARISON OF TWO DIFFERENT METHODS (FRAP AND TEAC) TO EVALUATE THE TOTAL ANTIOXIDANT CAPACITY IN THE SKIN MUCUS OF RAINBOW TROUT (*oncorhynchus mykiss*) IN RESPONSE TO ACUTE HYPOXIC STRESS

E. de Mercado[1*], I. Sanz[2], B. Martín[2], L.M. Laguna[2], A.M. Larrán[2], C. Tomás-Almenar[2]

[1]Department of Animal Reproduction, Instituto Nacional de Investigación Agraria y Alimentaria-CSIC, 28040 Madrid, Spain
E-mail: eduardo.mercado@inia.csic.es
[2]Aquaculture Research Centre, Agro-Technological Institute of Castilla y León (ITACyL), Segovia, Spain

**Introduction**

Skin mucus is an essential protective barrier for fish, whose production increases in response to environmental stressors and pathogens (Subramanian et al., 2007; Vatsos et al., 2010). The total antioxidant capacity (TAC) of skin mucus is a valuable, non-invasive biomarker for assessing the welfare of fish and understanding its physiological response to environmental challenges. Previous studies (de Mercado et al., 2018) showed that TAC, measured by the Ferric Reduction Activity Power (FRAP), changes in response to stress. However, TAC can be assessed by different methods that are sensitive to different groups of antioxidants. FRAP is based on the reduction of ferric ions ($Fe^{3+}$) to ferrous ions ($Fe^{2+}$) by antioxidants through a SET (Single-Electron Transfer) mechanism, making it especially sensitive to water-soluble compounds such as vitamin C, polyphenols and glutathione. In contrast, the TEAC (Trolox Equivalent Antioxidant Capacity) assay determines the capacity to neutralize the ABTS radical, both by the SET mechanism and by the HAT (Hydrogen Atom Transfer) mechanism, which allows it to detect a wider range of antioxidants. Given these differences, the study's objective was to compare the kinetics of the TAC response in rainbow trout skin mucus after acute hypoxia stress, using both the FRAP and TEAC assays to see if they provide different insights into the antioxidant response.

**Material and Methods**

Thirty rainbow trout (76.3 ± 2.6 g; length 17.9 ± 0.1 cm) were subjected to acute hypoxia stress, and skin mucus were collected at 4 time points, with six fish sampled per point: pre- stress (basal), immediately post-stress (time 0), and at 2- and 5-hours post-stress. The samples were collected and processed according to Mercado et al. (2018). FRAP analysis was performed using the method described by Benzie and Strain (1996), where reducing capacity was determined by measuring absorbance at 593 nm against a $Fe^{2+}$ standard curve. Results were expressed in µmol $Fe^{2+}$/g of skin mucus. The TEAC assay was analysed following the instructions of the commercial OxiSelect™ Trolox Equivalent Antioxidant Capacity (TEAC) Assay Kit (ABTS), and the absorbance was measured at 405 nm against a Trolox standard curve. Results were expressed in µmol Trolox/g mucus. Differences between time points were analysed using one-way analysis of variance (ANOVA) followed by Tukey's post hoc test. $P < 0.05$ was considered statistically significant.

**Results and discussion**

The different methods used showed a different response. The FRAP assay showed no immediate change in TAC after acute hypoxia stress (0H). However, a significant increase was observed at 2H post-stress respect to basal level ($P<0.05$), which subsequently decreased to intermediate levels at 5 hours (Fig 1). This delayed response suggests that the antioxidant response is not immediate. Conversely, the TEAC method detected no significant changes in TAC at any of the sampling times (basal, 0H, 2H, 5H) but showed similar values to those observed in with this technique by other authors (Guardiola et al., 2018; Tagami and Kuwahara 2020). Although a slight increase was observed at 0H, this was not statistically significant ($P>0.05$).

These results suggest that the antioxidant response to hypoxia in skin mucus can be multifaceted. The choice of assay is critical. FRAP could be more sensitive to water-soluble antioxidants and low molecular weight compounds that are mobilized or synthesized as a late response to hypoxic stress, while TEAC could detect more structural antioxidant compounds that are not easily or quickly modified. This highlights the need for further research to fully understand the complexities of this biological defence mechanism.

*(Continued on next page)*

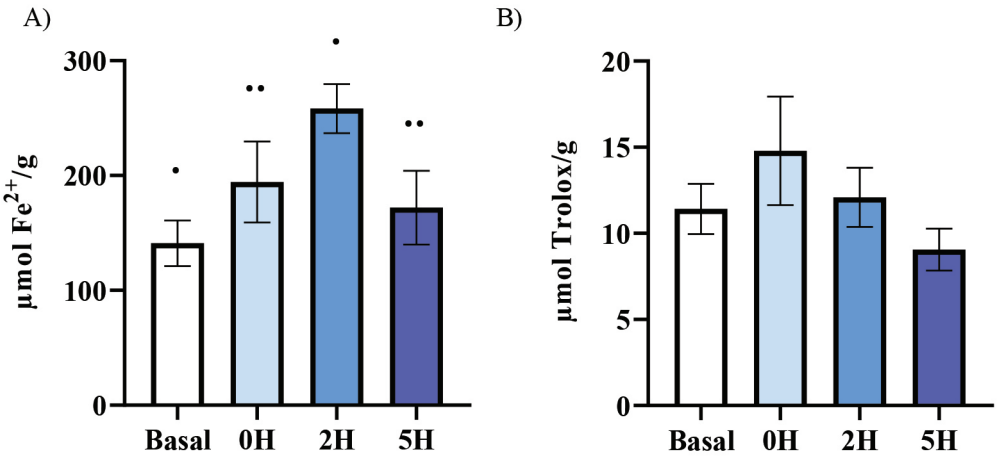

Fig 1. Evaluation of the total antioxidant capacity (TAC) in the skin mucus of rainbow trout (*Oncorhynchus mykiss*) at different time points: pre-stress (basal), 0H (immediately post-stress) and 2H and 5H post-stress. (A) FRAP values (µmol $Fe^{2+}$/g mucus). (B) TEAC values (µmol Trolox/g mucus). Data are presented as mean ± standard error (SEM). [a, b]Indicates statistically significant differences ($p < 0.05$).

## Introduction

With the ongoing growth of aquaculture, there is an increasing societal concern around reducing environmental impacts of production systems, particularly for rainbow trout (*Oncorhynchus mykiss*) the main fish species farmed in France (33082 tonnes; FAO, 2023). Addressing these concerns requires robust and standardized methods to assess such impacts.

Life Cycle Assessment (LCA) offers a standardized and comprehensive framework to evaluate environmental impacts of fish production systems by analysing material and energy flow across multiple impact categories. This method was extensively applied in previous studies on salmonids production (e.g., Chen et al, 2015; Pouil et al., 2024).

In this study, we applied LCA to assess the environmental impacts of rainbow trout farming in the Hauts-de-France region, currently the leading production area in France, with its share increasing from 21.9% in 2016 to 28.3 % in 2023 of national volumes (Agreste, 2019; Agreste, 2025) while this northern region may become increasing strategic for trout production in the climate change context as it is less affected by water scarcity.

## Materials and Methods

Between March and May 2025, eight rainbow trout farms using conventional flow-through systems in Hauts-de-France were surveyed. The data collected supported an attributional LCA following ILCD guidelines (JRC, 2010), with a cradle-to-farm-gate scope and a functional unit of one tonne of trout produced per year. Primary data came from on-site surveys; background data were sourced from Agribalyse 3.0 and Ecoinvent 3.3.1. The Life Cycle Inventory covered five subsystems: feed production, fry production, farm operations (i.e. use of facilities and equipments and emissions of pollutants from the biological transformation of fish feed), land emissions, energy use, and infrastructure. Environmental impacts were assessed across six categories: global warming (GWP), terrestrial acidification (TAP), freshwater eutrophication (FEP), marine eutrophication (MEP), land use (LU), water dependence (WD) using ReCiPe 2016 Midpoint (H) v1.07, and Cumulative Energy Demand (CED). To enable comparison with previous studies, the environmental impacts per tonne of trout produced were also assessed using the CML baseline methodology. The results were analysed to identify key contributors and compare the performance of the farms at a regional scale.

## Results

We observed marked differences in environmental performance per tonne of farmed trout between production sites, particularly in the TAP, FEP, and LU categories, where impacts varied by up to 2.5-fold (1.9 to 2.5 times) between the lowest (Site 2) and highest-impact (Site 6) sites. Across all sites, feed was the main contributor to environmental impact, accounting, on average, for GWP, 87% of TAP, 95% of LU, and 67% of CED. Farm operations were the main drivers of FEP (89%) and MEP (84%), as well as WD (85%). Other subsystems contributed only marginally.

The most notable change in the contributions between sites was linked to fish feed consumption and the intensity of liquid oxygen use responsible for 56 to 87 %, respectively 0.6 to 31% of GWP value. Electricity consumption (1.9-5.4%) and fry production (1-6.2%) also showed minor differences across sites.

*(Continued on next page)*

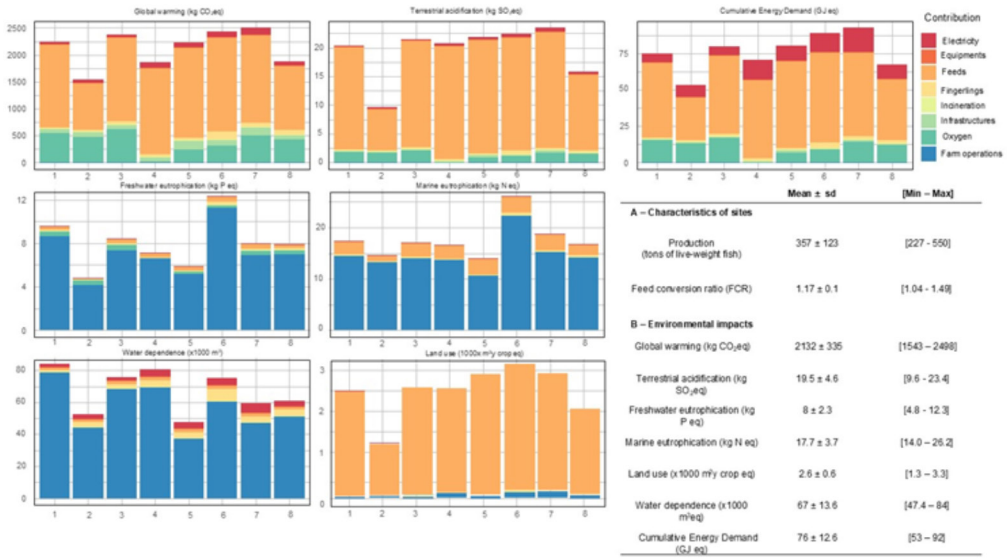

**Fig. 1.** Contribution of rearing system components to the environmental impacts (assessed using ReCiPe 2016 Midpoint (H) v1.07 methodology) of eight trout farms in Hauts-de-France. Results are expressed per tonne of live-weight trout at the farm gate. The figure includes site characteristics and values for the seven selected impact categories (mean ± standard deviation, min-max).

## Discussion

Environmental impacts assessed using the CML baseline methodology for the eight trout farms in Hauts-de-France were consistent with values obtained with the ReCiPe method and with values reported for conventional flow-through systems (reviewed by Pouil et al., 2024). A comparison with Chen et al. (2015), who surveyed 10 French farms producing between 100 and 500 tonnes annually, revealed higher regional averages in Hauts-de-France for TAP and CED (1.5 and 1.6 times higher, respectively), likely due to more energy-intensive equipment and operations. In contrast, water dependence was 1.7 times lower, possibly reflecting higher production intensities.

Feeds were among the main contributors to environmental impacts while variations in the contribution of feeds across sites were probably linked to differences in composition and transport distance. As expected, we found a strong correlation between FCR with impact levels across most categories.

This analysis forms part of a broader PhD project aiming to assess trout production impacts at the national scale. This work, carried out as part of the CoBreeding project and Metaprogramme Climae, received support from the French government managed by the National Research Agency under the France 2030 initiative, reference ANR-22-PEAE-0003.

# PATHOGEN-SPECIFIC DYNAMICS IN SHRIMP DISEASE MODELS: A COMPARATIVE STUDY OF INDIVIDUAL AND GROUP CHALLENGES FOR WSSV AND AHPND IN *Penaeus vannamei*

Evelien De Swaef[1*], Natasja Cox, João J. Dantas-Lima[1]

[1]IMAQUA
Ambachtenlaan 27A
9080 Lochristi, Belgium
*Correspondence: Evelien.Swaef@imaqua.eu

*Penaeus vannamei*, the Pacific whiteleg shrimp, is a cornerstone species in global shrimp farming due to its fast growth, adaptability, and high market demand. However, disease outbreaks, particularly those caused by White Spot Syndrome Virus (WSSV) and Acute Hepatopancreatic Necrosis Disease (AHPND), continue to represent major constraints to production (Brummett et al., 2014). While controlled and standardized experimental challenge models for these diseases are critical for evaluating prophylactic and therapeutic interventions, they are still scarce. For progressing on this topic, reliable detailed data on disease pathogenesis and dynamics is paramount. Comparative data on individual versus group challenge approaches - especially across different pathogens - can bring substantial added value to the process of the development and improvement of disease challenge models. However, these data remains virtually inexistent.

In this study, we established and compared both individual and group challenge models for WSSV and AHPND in *P. vannamei* under controlled laboratory conditions. Individual challenge models were designed to standardize pathogen exposure and assess the efficacy of health management products with high precision. Group challenge models, meanwhile, were developed to simulate more natural disease transmission dynamics and allow for broader application of candidate treatments.

For WSSV challenges, one peroral inoculation with WSSV-infected tissue inoculum (Thai-1 strain) (Thuong et al., 2016) was used in both individually housed (1 shrimp per 10L tank) and group housed challenges (100 shrimp per 290L tank and 10 shrimp per 10L). AHPND disease challenges were performed in the same setups but shrimp were inoculated via immersion with *Vibrio parahaemolyticus* TW01 (Alloul et al., 2021). Also in these cases, one single inoculation was performed. In both cases, animals were maintained for at least 10 days post inoculation and disease and mortality were monitored several times per day.

Striking differences were observed between pathogens and challenge models. During both the individual and group WSSV challenges, the Thai-1 strain had an incubation period of 24-54 hours post infection (hpi) and an irreversible disease progression within 78 hpi. In WSSV group challenges, a distinct pattern of reinoculation events was demonstrated, resulting in 100% final mortality in all cases (following a minimal stocking density). This progression differed markedly from the individual WSSV challenge, where mortality curves were less steep and final mortality much more limited, suggesting differences in infection dynamics and host response depending on the mode of exposure.

In contrast, AHPND challenges showed comparable disease dynamics between individual and group models. The *V. parahaemolyticus* TW01 strain resulted in mortality within 12 hours following inoculation, with an exponential mortality increase in the first 36 hours. Notably, AHPND did not result in irreversible disease progression in the early stages post-challenge. Mortality was variable depending on the trial and dosing, but final cumulative mortality stabilized between 50% and 85%. In addition, higher initial bacterial loads were required to establish consistent infections in AHPND group models in comparison with individual challenges, highlighting differences in infectious dose thresholds. This was not observed in WSSV challenge models at our facility. These findings underscore the importance of understanding pathogen-specific dynamics under different circumstances, when designing and interpreting challenge studies.

*(Continued on next page)*

This work emphasizes that while individual challenge models offer high reproducibility and control, group challenges better reflect field-like transmission and reinfection dynamics, especially in the context of WSSV. For AHPND, the choice of model may be less critical given the similar progression observed across methods, but attention to initial dosing remains essential. This strongly suggests that the transmission of WSSV between individuals plays a very important role in field outbreaks, while this seems to be less important in AHPND, where water transmission independently from the host might be of greater importance.

In conclusion, the choice of challenge model has a significant impact on disease outcome and must be tailored to the specific pathogen and research objectives. This study contributes valuable insights for the development and refinement of disease challenge protocols in *P. vannamei*, ultimately supporting more effective evaluation of health management strategies in shrimp aquaculture.

This research received partial funding from Flanders Innovation and Entrepreneurship (Belgium).

# SIMPLIFIED ROTIFER PRODUCTION: A KEY TO HIGH-QUALITY ROTIFER ENRICHMENT

T. De Wolf*[1], G. Franchi[1], M.Pierantozzi[1], E.Spagnoli[1], E.Pertoso[1], P.Cecconi[1] and G. Rombaut[2]

[1] INVE Aquaculture Research Centre, Via P.Gigli snc, 57016 Rosignano Solvay (LI), Italy

E-mail: t.dewolf@inveaquaculture.com

## Introduction

The production of high-quality live food remains a key success factor in many hatcheries for marine finfish species. The required rotifer quantities, needed to successfully produce fish larvae, have decreased in the last years, thanks to the development of high-quality, partial rotifer substitution diets such as Natura pRo (INVE Aquaculture, Thailand). Because of this trend, it is of uttermost importance that the provided rotifers are of high nutritional and microbial quality and that the procedures to produce them are easy and limited in time. In this work is presented how rotifer culture and enrichment combinations, using the correct products, can result in optimal live prey for the rearing of Seabream larvae.

## Materials and methods

*Rotifer culture and enrichment*

L-type rotifers were cultured in cylindroconical tanks of 850L at a temperature of 26°C and a salinity of 25ppt. The culture tanks were equipped with aeration in order to provide a homogeneous distribution of the rotifers and rotifer diets. Dissolved oxygen levels were kept between 80 and 150% of saturation. Rotifers were cultured using three different feed combinations, each designed to optimize the cultivation process:

1. 90% Fresh Baker's Yeast/10% RoBoost = (Control or CTR)
2. 100% VitAlgae Nanno (=Vitalgae Nanno)
3. 90% VitAlgae Nanno/10% RoBoost (=Vitalgae/Rob)

The required rotifers for Seabream larvae were enriched directly in the same culture medium, without a harvesting or rinsing step, at a density of 1000-1500 rotifers per ml. This enrichment was performed using Easy Dry Selco (INVE Aquaculture, Thailand), up to 2x145 ppm for a duration of 12 hours. At harvest, rotifers were rinsed and stored in cold storage (6-8°C) for the different feedings during the day.

*Seabream Larval rearing*

For each treatment, three replicate tanks of 1000L were stocked with 80 000 just-hatched Seabream larvae, all originating from the same pool of eggs. The larvae were reared at a temperature of 19±0.5°C in seawater with a salinity of 38ppt. From 3 to 20 days post hatch (dph), approximately 60-70g of VitAlgae Nanno per m³ were added daily to the tanks followed by a daily ratio of 15 grams of Sanolife GWS (INVE Aquaculture, Thailand) per m³ between 21 and 30dph. In all tanks, the larvae were fed following the traditional feeding protocol, using rotifers (produced according to the three different treatments) from 3 to 30dph, AF SEP-Art Artemia from 16 to 26dph and EG SEP-Art, enriched with Easy Dry Selco, from 23 to 55dph. At 19dph a dry diet (O.Range, INVE Aquaculture, Thailand) was introduced and fed until the end of weaning (55dph).

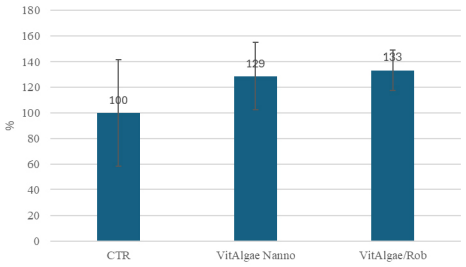

Fig.1. Relative rotifer production over a three-day batch culture period

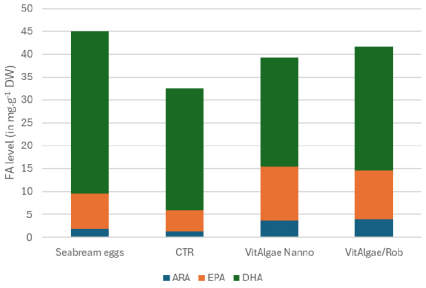

Fig.2. EPA, ARA, DHA Levels in Enriched Rotifers Compared to Seabream Eggs

*(Continued on next page)*

*Evaluation parameters*
The growth performance and nutritional profile of the rotifers were evaluated for all treatments.

For the Seabream larvae, survival rate, growth parameters, stress resistance, deformity levels and FAME values were assessed. Larvae were weaned at 55 dph and fish from all tanks were graded to determine the survival and quality of the fry produced.

**Results**
The average rotifer production over a three-day batch culture period, expressed in millions of rotifers reproduced per 1000 liters, was approximately 30% higher for treatments containing VitAlgae Nanno compared to the control treatment (see Fig.1).

FAME analyses for the essential fatty acids performed on the Seabream eggs and on the enriched rotifers from the three treatments, are presented in Fig.2. The sum of essential fatty acids (EPA, ARA and DHA) present in rotifers enriched with Easy Dry Selco directly in the rotifer culture medium after using VitAlgae Nanno either at 100% or as 90% (with 10% Rob), is similar to the levels found in Seabream eggs, and higher compared to the control rotifers. Regarding the performance of the Seabream larvae, all treatments yielded similar survival rates. The growth rate at the end of the rotifer phase was slightly higher for the treatments using VitAlgae Nanno, compared to the control treatment, as evidenced by both length and dry weight measurements. At 30 dph, fish larvae from treatments containing VitAlgae Nanno demonstrated better resistance when exposed to a salinity stress test than the control larvae, however, these differences were not apparent by the end of the weaning period. Histological staining analysis of early deformity levels at a total length of 10-12mm, did not reveal any differences between the treatments.

**Conclusions**
These results highlight the importance of high-quality rotifer culture and enrichment products in maintaining optimal larval development and performance, especially as the quantity of rotifers used in larval fish protocols decreases due to the introduction of new larval diets. As a conclusion it can be stated that the use of VitAlgae Nanno, RoBoost and Easy Dry Selco, applied during a combined culture and enrichment process for rotifers, results in a rotifer quality that is suitable for a successful larval rearing of Seabream larvae. These procedures, significantly reduce the manpower and resources, needed to produce high-quality rotifers without compromising the quality of the fry produced.

# MODULATION OF ARTEMIA MICROBIOTA THROUGH PROBIOTIC ENRICHMENT: A STRATEGY TO ENHANCE BIOSECURITY IN MARINE LARVICULTURE

De Wolf T*.[1] , Pierantozzi M.[1] , Cecconi P. [1] , Franchi G.[1] Hostins B.[2] and Rombaut G.[2]

[1] INVE Aquaculture Research Centre, Via P.Gigli snc, 57016 Rosignano Solvay (LI), Italy
[2] INVE Technologies NV, Hoogveld 93, 9200 Dendermonde, Belgium
E-mail: t.dewolf@inveaquaculture.com

## Introduction

The increasing demand for fry is driving hatcheries to intensify production, often resulting in high rearing densities. Under such conditions, health management and microbiological control are crucial and essential factors for successful larval rearing. Among the many aspects to consider when defining a biosecurity plan, the management and control of live feed (primarily rotifers *Brachionus plicatilis* and brine shrimp *Artemia franciscana*) play a central role.

This study aimed to evaluate the effectiveness of a combined protocol based on the use of EG SEP-*Art*™ D-FENSE Artemia and a probiotic enrichment (Sanolife® MIC-F, INVE Aquaculture, Belgium) containing *Bacillus licheniformis, B.subtilis* and *B.pumilus,* to modulate the microbiota associated with *Artemia*, thereby contributing to improved larval health and biosecurity.

## Materials and Methods

Three enrichment strategies were tested:
**Control**: EG SEP-*Art*™ Artemia enriched without probiotic addition
**Probiotic Enrichment in Matured Water**: EG SEP-*Art*™ D-FENSE Artemia enriched in matured water with 1 $g.l^{-1}$ MIC-F (without prior activation) added 2 hours before nauplii introduction
**Post-Harvest Probiotic Treatment**: EG SEP-*Art*™ D-FENSE Artemia enriched under standard conditions, followed by treatment with activated MIC-F (2.5 $g.l^{-1}$, 5000 $nauplii.ml^{-1}$).

For treatment 3, Bacillus spores were activated at 30°C during 1 hour and subsequently added to the Artemia metanauplii suspension at 25°C. After 30min a gradual temperature decrease was initiated in order to reach 6°C within 1 hour. Artemia metanauplii were further stored at 6°C in a cold storage unit for 5 hours.

Microbial samples were collected at the end of enrichment (21h), and for treatment 3, additional samples were taken after 1h and 6h of cold storage. Microbiota composition was analyzed using 16S rRNA gene sequencing, enabling taxonomic classification and relative abundance profiling.

## Results

Microbial analysis revealed a significant reduction in Proteobacteria, the phylum that includes *Vibrio* spp., in both probiotic-treated groups, compared to the control. Concurrently, an increase in Firmicutes—containing the *Bacilli* spp.—was observed, indicating a shift toward a more favorable microbial profile. Furthermore, during the cold storage period, the relative abundance of Firmicutes continued to rise, while the Proteobacteria declined.

These shifts suggest that both probiotic strategies can effectively modulate the microbial community of *Artemia*, with potential implications for larval health.

## Discussion

The ability to influence the microbiota of live feed offers a valuable tool for hatchery managers aiming to reduce disease risk and improve larval performance. The observed reduction in Proteobacteria (including *Vibrio* spp.), combined with the enrichment of beneficial taxa, supports the use of targeted probiotic protocols as part of integrated biosecurity strategies.

Treatment 3, involving post-harvest contact with activated *Bacillus* spores, appears particularly promising due to its rapid and effective microbial modulation, even under cold storage conditions. This flexibility could facilitate operational integration in commercial hatcheries.

## Conclusions

Probiotic enrichment of *Artemia* using Sanolife® MIC-F demonstrates a clear potential to modulate microbial communities in favor of beneficial taxa, reducing the prevalence of potentially pathogenic bacteria. This approach contributes to enhanced biosecurity and supports the sustainability of intensive marine larviculture systems.

# HEART OEDEMA IN NEWLY HATCHED LARVAE: A TRANSCRIPTOMIC INSIGHT

Rossella Debernardis [1*], Katarzyna Palińska-Żarska[2], Sylwia Judycka[1], Abhipsa Panda[1], Taina Rocha de Almeida[1], Christophe Klopp[3], Daniel Żarski [1]

[1] Team of Development and Reproduction in Fish, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Poland

[3] Sigenae, UR875, INRAE, Castanet-Tolosan,France
*Presenting author: e-mail: r.debernardis@pan.olsztyn.pl

**Introduction**

Aquaculture continues to face challenges in producing high-quality larvae and early developmental deformities, often leading to high mortality and reduced production efficiency (Boglione et al., 2013; Chandra et al., 2024), are among major concerns. Variation in the type and occurrence of deformities across species, populations, and even within families complicates efforts to study and understand their underlying causes. While deformities are generally linked to genetic, biological, and external factors, those occurring immediately after hatching are more likely to result from genetic or non-genetic parental influences (Adrian-Kalchhauser et al., 2020). Among others, heart oedema is one of the most common deformities and is often expressed as a lethal trait. In Eurasian perch (*Perca fluviatilis*), this condition, marked by fluid build-up around the heart, is often observed in larvae obtained from spawners grown in recirculating aquaculture systems (RAS), impairing their cardiovascular function (Alix et al., 2017). Despite its prevalence, its underlying mechanisms remain poorly understood. This study aims to compare the within-family transcriptomic profiles of normal-shaped newly hatched larvae with those exhibiting heart oedema, offering insights into its molecular basis and potential strategies for improving broodstock management and larval quality.

**Materials and Methods**

Eurasian perch larvae from 8th-generation domesticated broodstock reared in RAS were used. Eggs were fertilized *in vitro* using cryopreserved milt and incubated under controlled conditions. On the day of hatching, larvae showing heart oedema and normal-shaped siblings were selected from 5 different families. Total RNA was extracted from each family and phenotype, and sequenced (10 libraries, 150 bp paired-end, 40M reads per library). Differentially expressed genes analysis was performed using DESeq2. Gene ontology enrichment (GO) was conducted with ShinyGO. Heart-specific genes were identified using PhyloFish database and further validated by RT-qPCR.

**Results**

Heart oedema has been found to be a lethal trait in Eurasian perch. Transcriptomic analysis revealed 507 differentially expressed genes (DEGs; $p < 0.05$, $\log_2 FC > 1$). GO analysis of DEGs indicated strong enrichment in metabolic regulation, stress response, and DNA repair. Seventeen heart-specific DEGs ($\tau > 0.85$) were selected for RT-qPCR validation. Their expression was tracked across key embryonic developmental stages to assess their role in cardiac development. Among these, *arl14, hbz* and *c18orf21* has been positively validated with qPCR. Developmental profiling showed lack of these genes in unfertilized eggs, low expression levels shortly after fertilization, with a noticeable increase around 100 hours post-fertilization (tail detachment stage), followed by a sharp rise at approximately 7 days post-fertilization, corresponding to the eyed-egg stage.

**Discussion**

This study provides novel insights into the processes underlying larval cardiac deformities and offers a foundation for developing strategies to mitigate mortality and improve aquaculture outcomes. The presence of both heart-oedema and normal larvae within the same family, sharing the same genetic background, suggests complex interactions between parental gametes, which we term 'parental dispute' (Debernardis et al, 2024). This highlights the crucial role of gamete-derived non-genetic factors underlying heart oedema. Additionally, the genes validated through qPCR emerge as strong candidate markers for further investigation into cardiovascular development and stress responses in fish embryos. Profiling their expression at critical embryonic stages revealed that their expression starts after zygotic genome activation and is associated with further heart morphogenesis (Alix et al., 2015). Our results suggest that disruptions in gene regulation during these stages may contribute to heart oedema.

Overall, these findings enhance our understanding of larval deformities, emphasizing the role of non-genetic inheritance factors in shaping larvae quality in E. perch.

# USE OF SUGAREX AQUA TO MITIGATE NEGATIVE IMPACTS OF LOW-PALATABILITY AND MEDICATED FEEDS IN ATLANTIC SALMON (*Salmo salar*)

S. Deguara[2], F. J. Crespo Montero[1], A. Armatore[2], D. Romaní López[1]

[1] HealthTech Bio Actives, S.L.U., Avenidai Diagonal, 567 4th Floor, 08029 Barcelona, Spain
[2] AquaBioTech Group, Central Complex, Naggar Str., Mosta MST1761, Malta
Email: dsd@aquabt.com

## Introduction

Dietary changes can negatively affect feed intake in fish, leading to suboptimal performance. To address issues of palatability, various feed additives have been explored. Sugarex AQUA is a proprietary neohesperidin dihydrochalcone (NHDC) formulation with enhanced solubility and sensory properties. Research in other livestock has shown that NHDC, can enhance feed intake and improve growth performance. However, data on its effects in aquaculture remain limited. This study aimed to evaluate the impact of Sugarex AQUA on feeding behaviour and performance of Atlantic salmon (*Salmo salar*) when added to low-palatability or medicated diets.

## Materials and Methods

Groups of 30 162g Atlantic salmon (*Salmo* salar) were held in 30 500 L holding units forming part of a recirculating aquaculture system (RAS) with full strength sea water having a target temperature of 13 $\pm$ 1$^{o}$C and a with a light/dark cycle of 12/12 h. The trial was split into four two-week periods and the fish in each holding tank were weighed in bulk every two weeks. Feeding behaviour was assessed using a fixed scoring system.

Six treatments were tested with five replicates per treatment. The first set of treatments consisted of a control diet formulation with or without supplemental Sugarex AQUA (CD and CDS respectively). The second set of treatments consisted of a low-palatability diet with or without supplemental Sugarex AQUA (LP and LPS respectively). The final set of treatments were similar to the first two treatments except during the second two-week period during which an antibiotic (oxytetracycline) was added to the feed with or without supplemental Sugarex AQUA (TM and TMS respectively). Sugarex AQUA concentration in the supplemented diets was 0.6 g/kg, equivalent to an inclusion level of 18ppm NHDC.

Data was checked using Shapiro-Wilk and Levene's tests. T-tests or Mann-Whitney U tests (https://www.statskingdom.com) were used to compare similar diets ($p < 0.05$).

## Results

No significant differences in fish weight or specific growth rate (SGR) were observed between fish fed diets CD and CDS. Feed intake was slightly higher in CDS-fed fish, and feed conversion ratio (FCR) was consistently improved. Sugarex AQUA inclusion gave an SGR and FCR improvement of 8% and 4%, respectively. Sugarex AQUA had a more pronounced effect on fish fed the LP diets, significantly improving fish growth in Periods 1 to 3. Feeding behaviour and feed intake were also significantly higher in LPS-fed fish. In Periods 2 and 3, fish fed the TMS diet clearly outperformed those on the TM diet, showing significantly higher SGRs. Although the difference in SGR was not statistically significant in Period 4, the TMS group maintained a stronger overall growth, with a SGR 26% higher than the TM group. From Period 2 onwards, feed intake and SFR were consistently better in the TMS group, remaining significantly higher through to the end of the trial. Additionally, fish fed TMS achieved better feed efficiency, with FCR being consistently lower than the TM group in all periods, most notably in Period 3, resulting in a 13% overall reduction in FCR compared to the TM diet.

## Discussion

There were no clear benefits of adding Sugarex AQUA to the control diet. Conversely, Sugarex AQUA had a clear positive effect on feed intake and overall performance when included in the low-palatability diet for fish. The greatest impact was observed in Periods 1 and 2, diminishing over time, likely due to adaptation to the taste of the low-palatability formulation.

*(Continued on next page)*

The results related to Sugarex AQUA use alongside antibiotics were also clear. No significant differences were observed in Period 1 but, when antibiotics were introduced in Period 2, feed intake and SGR significantly increased in the Sugarex AQUA-supplemented group. It was expected that, once antibiotics were discontinued, the differences between the two treatments would disappear. However, significant differences in feed intake and performance persisted through Periods 3 and 4 and across the entire trial period. These results suggest that antibiotic use may have had a lasting impact on fish performance even after treatment ceased. This effect could be attributed to changes in gut microbiota (Dhanasiri et al., 2024; Monticelli et al., 2024), although this was not investigated in this study. Over the full trial period, fish fed the medicated diet (TM) were significantly smaller and exhibited lower growth than those fed either the control diet (CD) or the Sugarex AQUA-supplemented control diet (CDS). On the other hand, NHDC has been shown to positively influence gut morphology and microbiota (Daly et al., 2016; Wang et al., 2024), which may have helped mitigate the negative effects of the TM diet. As a result, by the end of the experiment, there were no significant differences in SGR and FCR between fish fed TMS and those on the control diets with or without Sugarex AQUA.

**Conclusions**

The findings of this study indicate that Sugarex AQUA can be beneficial in two key situations commonly encountered in aquaculture:

- Dietary Changes: Sugarex AQUA can help maintain feed intake and performance when feed formulations change due to ingredient availability, cost fluctuations, etc.
- Antibiotic Use: Sugarex AQUA supplementation can counteract the reduction in feed intake associated with antibiotic treatments.

## Introduction

Integrated Multitrophic Aquaculture in Recirculating Systems (IMTA-RAS) with macroalgae can mitigate the environmental impacts of fish production. *Ulva* spp. efficiently absorb nutrients, such as nitrate and phosphate, and transform them into biomass for food, feed or bioactive molecules. Moreover, the introduction of *Ulva* spp. can potentially modify the microbiome of the whole system. It is known that *Ulva*'s laminar blade offers support for beneficial bacteria, such as *Phaeobacter* spp., antagonists of fish pathogens. To understand the impact of *Ulva* on the system's microbiome, a holistic analysis of the microbiome was conducted in a commercial-scale pilot scale system.

## Materials and Methods

Two sequential trials were performed: one with sole fish (*Solea senegalensis*) in a RAS, and a second integrating sole with sea lettuce (*Ulva ohnoi*) (IMTA-RAS). The global microbiome of RAS and IMTA-RAS were compared using 16 rRNA metagenomic approach, which included samples taken from sea lettuce, sole (skin, gills, distal intestine mucosa), feed, , and the culture system (tank walls, biofilter and recirculating water). The study also included the analysis of parameters of the fish (growth, welfare markers and quality), the *Ulva* (growth and biochemical composition) and water (physicochemical parameters, nutrients) in order to establish, in future work, possible correlations.

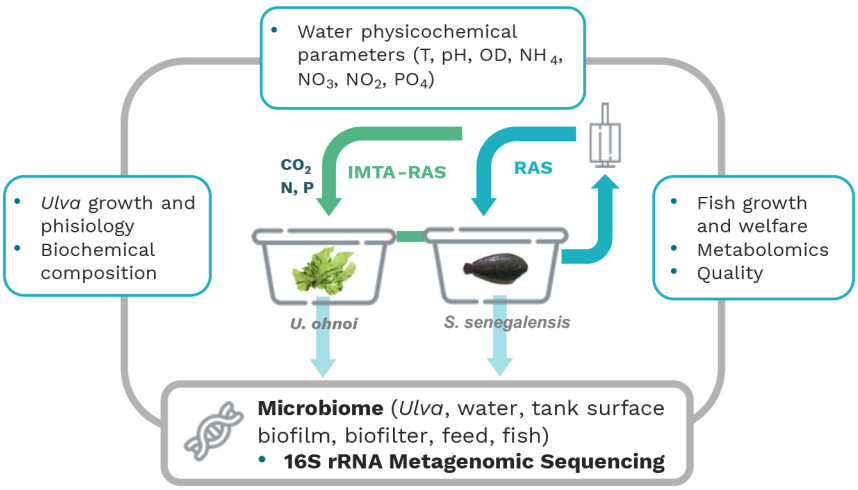

Fig. 1: Experimental design

*(Continued on next page)*

## Results

The results showed that the introduction of *U. ohnoi* significantly affects the microbiome of the system, including the one in the recirculating water, in the biofilter and in the biofilms of the tank walls, by altering both diversity metrics and taxonomic composition. Water samples taken before the biofilter consistently showed higher richness and diversity than those collected after ther biofilter, regardless of system type. Over time, beta diversity analyses revealed differences between RAS and IMTA-RAS in water microbiome at all timepoints and across compartments. Water in IMTA-RAS system was enriched in genera such as *Ruegeria*, *Vibrio*, *Maribacter*, *Polaribacter*, and *Sulfitobacter*. Some of these genera are associated with probiotic traits, biofilm stabilization, or antagonism against fish pathogens, suggesting potential health benefits. In the biofilter, microbial composition shifted temporally. At initial stages, *Roseovarius* dominated in RAS, while IMTA-RAS showed higher abundances of *Maribacter*, *Sulfitobacter*, and members of *Bdellovibrionaceae*. By the final sampling point, RAS was characterized by the presence of *Hyphomonadaceae*, whereas IMTA-RAS continued to support *Rubidimonas* and *Sulfitobacter*, the latter being consistently present and linked to sulfur metabolism and antimicrobial properties. Biofilms on fish tank walls also responded to *U. ohnoi* introduction. IMTA-RAS biofilms showed higher microbial richness and diversity, especially in early stages. *Nitrospira*, a genus involved in nitrogen cycling and known to contribute to biofilm stability, was dominant in IMTA-RAS, potentially enhancing system resilience. In contrast, RAS biofilms became dominated by *Thiothrix* at the final timepoint, a genus frequently linked to sulphide production and biofouling issues, which may indicate undesirable microbial development in RAS. These microbial shifts indicate that the inclusion of *U. ohnoi* may favour a more stable and functionally beneficial microbial community, potentially contributing to improved system health and pathogen resistance. Regarding the effect on fish, the analysis of the microbiome of *Solea senegalensis* is still ongoing. However, recent published results (Molecules 2025, 30(12), 2518) of metabolomic analysis of *S. senegalensis* muscle from those experiments revealed enhanced energy metabolism in IMTA-RAS systems, suggesting increased overall metabolic activity. These findings are promising, and upcoming microbial analysis may help establish a link between the systemic microbial environment and fish physiology, offering insights into the functional benefits of integrated multitrophic aquaculture.

## Conclusions

The integrated analysis of the results will allow an understanding of the changes in the microbiome of the systems and demonstrate the potential effect of IMTA-RAS on fish health and welfare. By operating IMTA-RAS systems, the aquaculture sector could diversify, decrease its environmental footprint, and producing in a healthier way.

## Acknowledgments/Funding

The project was funded through Xunta de Galicia with NextGenerationEU and the European Maritime Fisheries and Aquaculture Funds, within the Galicia Marine Science programme, Complementary Science Plans for Marine Science of Ministerio de Ciencia e Innovación, included in the Recovery, Transformation and Resilience Plan (PRTR-C17.I1). L.B. was beneficiary of a Juan de la Cierva Formación grant by the Ministerio de Ciencia e Innovación (FJC2021-047947-I). G.D.O was beneficiary of a grant from the Axencia Galega de Innovación (IN606A-2021/038).

# COMBINED THERAPEUTIC STRATEGIES AGAINST *Piscicketsia salmonis* IN *Salmo salar*: EVALUATION OF THE SYNERGISTIC POTENTIAL BETWEEN FLORFENICOL AND A PHYTOGENIC ADDITIVE

Delgado, Marcela Paz* [1,2,] Schwerter, Alan.[1], Delgado, Lorena.[1,2], Asencio, Leslie[1]

[1] Sudvet corp, 25030 Av. Tibbitts, Suite K, Valencia, Santa Clarita CA91355, USA
mdelgado@sudvetspa.com

The botanical product evaluated in this study represents an innovative and sustainable formulation as an alternative to the use of antibiotics in aquaculture. Its combination of organic acids and plant extracts has demonstrated effective antimicrobial properties, as well as supporting fish welfare, ensuring the quality of the final product and reducing the risk of bacterial resistance.

To evaluate its effectiveness, the administration of Florfenicol at 20 mg/kg for 10 days was compared with a reduced dose of Florfenicol (10 mg/kg) combined with the natural product, in Atlantic salmon (*Salmo salar*) experimentally infected with *Piscirickettsia salmonis*. The challenge was performed by intraperitoneal inoculation using two genetically distinct strains: LF-89 and EM-90, recognized for their difference in virulence and pathological patterns. Variables such as mortality, bacterial load, immunological parameters and histopathological indicators were evaluated.

Histopathological analyses revealed that the LF-89 strain predominantly produces kidney and liver lesions, while EM-90 generates a more systemic effect, with hemorrhages in multiple organs. Variables such as mortality, immunological markers, bacterial load and general health indicators were evaluated.

During the test, the fish maintained an intake greater than 1.5% of their body weight and no relevant biometric alterations were observed. Clinical signs appeared between days 20 and 26 post-inoculation in the positive control group, with a cumulative mortality of 40% at day 37. In contrast, both the botanical + Florfenicol combination and Florfenicol alone reduced mortality to 6.7%, equaling the negative control.

Both treatments also achieved a significant reduction in bacterial load. The combination with the botanical product at half dose of the antibiotic obtained an efficacy comparable to treatment with Florfenicol at full dose. This suggests a synergistic action that enhances the effect of the antibiotic and stimulates the immune system. Complementing these results, a field study conducted on *Oncorhynchus kisutch* showed that the exclusive use of the botanical product significantly decreased the scores of oxidative stress, inflammation and deficient immunocompetence. In addition, better integrity of the skin, fins and mucus, as well as a reduction in external injuries.

In conclusion, the botanical product presents a promising and sustainable approach to the control of *Piscirickettsia salmonis* in Atlantic salmon, allowing to reduce the use of antibiotics by up to 50% without compromising the efficacy of the treatment.

# EVALUATION OF A BOTANICAL FORMULATION AS AN IMMUNOPROTECTIVE AND ANTIMICROBIAL STRATEGY IN *Salmo salar* CHALLENGED WITH *Piscirickettsia salmonis*

Delgado, Marcela Paz* [1,2,] Schwerter, Alan.[1], Delgado, Lorena.[1,2], Asencio, Leslie.[1]

[1] Sudvet Corp, 25030 Av. Tibbitts, Suite K, Valencia, Santa Clarita, CA 91355, EE. UU

mdelgado@sudvetspa.com

Salmon Rickettsial Septicemia (SRS), caused by *Piscirickettsia salmonis*, is one of the main bacterial diseases in Chilean salmon farming. It generates high mortality rates and production losses, which has driven the search for more sustainable therapeutic alternatives.

This study evaluated the efficacy of a broad-spectrum natural botanical formulation designed to inhibit bacterial growth through multiple mechanisms: disruption of quorum sensing signaling, alteration of membrane integrity, and inhibition of protein and nucleic acid synthesis. In addition, it sought to enhance the fish's immune defenses, as well as reduce inflammation and oxidative stress.

The trials were carried out in farming centers in southern Chile. Groups of *Salmo salar* were fed the formulation for 30 days and then challenged with *Piscirickettsia salmonis* (strains LF-89 and EM-90) for another 30 days. Mortality rates, prevalence of infection, and physiological, histological and molecular analyses were carried out.

The treated fish showed a 64% reduction in infectious mortality compared to the control group. Significant activation of immune markers related to salmon rickettsial septicaemia (SRS), including CD4, CD8, IFN-γ, TNF, IL-1β, IL-10, lysozyme, and transferrin, was evidenced, indicating a potentiated adaptive immune response. Likewise, a decrease in oxidative stress was observed, reflected in lower activity of antioxidant enzymes in NFEL2, SOD3, CAT, GPX markers and in the reduction of the expression of genes associated with epithelial damage in the intestine, skin and gills, reflected by MMP2, MMP13, COL1A1.

From the histological point of view, the treated fish had higher intestinal villi height, less inflammation in enteric mucosa and greater density of mucosal cells in the skin, which suggests an improvement in the absorption capacity and in the barrier function against external agents (pathogens and inflammatory). In addition, a significant decrease in the general histopathological score was observed**,** with marked reductions in the levels of necrosis, inflammatory infiltration, and tissue damage, especially in the liver, kidney, and spleen.

Positive differences were observed in terms of production parameters, such as a 17% increase in growth and -7% FCR (feed conversion rate).

Taken together, these findings support the use of this botanical formulation as an effective and sustainable strategy for the management of *Piscirickettsia salmonis*. Its use significantly reduces mortality and strengthens the overall health of the fish, while minimizing the need for antibiotics and the associated risk of antimicrobial resistance in salmon farming.

# EVALUATION OF FRESHWATER IMMERSION TREATMENTS FOR FUNGAL AND FLAVOBACTERIUM INFECTIONS IN FISH: A WELFARE PERSPECTIVE

*Delgado, Marcela Paz** [1,2], Schwerter, Alan.[1], Delgado, Lorena.[1,2], Asencio, Leslie [3]

[1] Sudvet corp, 25030 Av. Tibbitts, Suite K, Valencia, Santa Clarita CA91355, USA
mdelgado@sudvetspa.com
[2] Nordvet SpA, Imperial 0655, Puerto Varas, Chile
[3] Innovogen, Egaña198, Puerto Montt, Chile.

Fungal infections and flavobacteriosis are significant health challenges affecting *Salmo salar* in aquaculture systems, during freshwater phases. These pathogens can compromise fish welfare, cause lesions, and increase mortality if not promptly managed. Salt baths, Bronopol and Formaline are commonly used as a curative and preventive treatment, yet their impact on animal welfare remains underexplored. Understanding the effectiveness and welfare implications of such treatments is critical for sustainable fish health management. This study evaluated the effect on animal welfare and health of two conventional preventive and curative treatments in fresh water, Salt at 2%, Formalin at 150 ppm and 40 ppm of Bronopol with AQBiocare Plus®, a naturally formulation derived of plants with antimicrobial broad spectrum with antioxidant and anti-inflammatory properties. The in vitro and in vivo studies in Atlantic salmon demonstrated the antibacterial efficacy against key pathogens, including Flavobacterium and Saprolegnia. In vitro studies validated through absorbance and MIC assays that AQ Biocare Plus® shows strong antimicrobial activity lasting 24 to 48 hours during immersion treatments and on fungal the doses of inhibiting to Saprolegnia were 50 ppm.

Beyond its antimicrobial properties, AQBiocare Plus® enhances innate immune responses, and takes care of the production and quality of the skin mucus, promoting disease resistance. It significantly strengthens natural immunity by improving cutaneous, mucosal, and serum immune parameters while upregulating immune-related genes. At the molecular level, it enhances inflammatory, immune, antiviral, and antibacterial responses while mitigating oxidative stress by reducing and scavenging free radicals. The markers of anti-inflammatory AqBiocare showed a stable response (IL1b, IL10, TNFa,) and tissue remodeling indicators (Col1A1, MMP2, MMP13) suggested a reduced skin damage compared with Formaline and Salt. The formulation also demonstrates superior control over reactive oxygen species (ROS), resulting in reduced oxidative stress, with lower activity of NFEL2, SOD3, GPX, and CAT, alongside high lysozyme levels, indicating enhanced bacterial protection. Fish treated with AQBiocare Plus® showed improved physiological balance, with up to 25% lower cortisol and 18% lower glucose compared to Salt or Formalin. Welfare biomarkers remained stable even under smoltification stress, indicating enhanced stress resilience.

Histologically, AQ Biocare Plus® increases mucous cell density in the skin, improves the quality and the quantity of the mucus, strengthening the fish's natural barrier, it has better effect on Lizozime. Welfare analyses, including serotonin, cortisol, lactate, glucose and osmolality measurements, highlight its positive impact on fish well-being.

These comprehensive benefits position AQ Biocare Plus® as an innovative and sustainable alternative in salmon farming, effectively protecting fish health, enhancing productivity and improving animal welfare.

# INNOVATIVE NON-PHARMACOLOGICAL APPROACHES FOR MANAGING *Caligus rogercresseyi*: IMPLICATIONS FOR THE HEALTH AND WELFARE OF ATLANTIC SALMON

Delgado, Marcela Paz[1,2], Schwerter, Alan [1,2], Delgado, Lorena [1]

1 Sudvet corp, 25030 Av. TibbiIs, Suite K, Valencia, Santa Clarita CA91355, USA
mdelgado@sudvetspa.com
2 Nordvet, Imperial 0655, Puerto varas, Chile

Global aquatic animal production has increased substantially since 1950, reaching 185 million tonnes in 2022, with aquaculture contributing over 51% of total output. In Chile, Atlantic salmon (Salmo salar) dominates the export-oriented aquaculture industry but faces major health challenges, especially caligidosis caused by the ectoparasite Caligus rogercresseyi. This parasite disrupts immune, neuroendocrine, and metabolic functions, reducing fish welfare and causing economic losses. Concerns over drug resistance, environmental impact, and animal welfare have driven interest in sustainable, non-pharmacological alternatives.

This study assessed the antiparasitic efficacy and physiological benefits of Rosseus Plus®, a botanical supplement based on essential oils and plant extracts, administered via therapeutic baths and water exposure. In vitro assays showed 93–100% effectiveness against adult C. rogercresseyi, while field trials using wellboats achieved parasite reductions of 98% in adults and 85% in juveniles. Waterborne delivery enhanced immune responses, lowered stress markers, and improved the intake of the feeding and the growth.

Molecular, histological, and physiological analyses revealed significant reduction in acute and chronic stress, mitigation of oxidative stress, lowering inflammation in gill and skin. Treated fish maintained stable cortisol levels, preserved lysozyme activity, uncompromised immune response, balanced osmoregulation and consistent serotonin concentrations, indicating improved neuroendocrine balance and welfare. The inclusion of antioxidant, serotonergic biomarkers provides a robust, science-based framework to monitor fish resilience and welfare, offering precise evaluation of health and treatment effects.

These findings support Rosseus Plus® as a safe, effective, and environmentally sustainable strategy for integrated parasite management in Atlantic salmon aquaculture, promoting welfare-focused and responsible production practices.

# TEMPERATURE EFFECT ON MICROBIAL COMMUNITIES AND CULTURED PIKEPERCH LARVAE UNDER COMMERCIAL CONDITIONS

Ferenc Zoltán Demény[1], Júlia Clols-Fuentes[2], Patrick Unger[2], Mathias Wolf[2], Harry W. Palm[2], Marcus Stüeken[1]

**Introduction**

Pikeperch (*Sander lucioperca* (L., 1758)) is a promising candidate for the diversification of inland aquaculture in Europe, although the production of sufficient fingerlings remains a bottleneck. The most critical stage of life during fish production is the larval period. Numerous factors regulate the larval survival, including environmental parameters (e.g. water quality, water temperature, and photoperiod), nutritional – (e.g. feeding frequency, weaning strategy), and population factors (e.g. stocking density).

The microbial environment of fish larvae is an additional factor that may determine the production success, since the microbes interact with the larvae at different levels. Microbes with an external origin (water and feed) will colonise the digestive tract of the fish and therefore influence the health status of the animal. The microbial community from the intestine of teleosts, namely fish gut microbiome, is an important element, ensuring the proper growth and health. However, in order to ensure economic production, the animals are confronted with various challenges. These include switching from live feed to commercial dry feed, called the weaning process. The microbiome changes abruptly with the habituation to dry feed. The status of the environmental and gut microbiome during this process under different feeding regimes and environmental conditions is still not evident in pikeperch. Information about microbial communities could provide key aspects related to the fish larvae production.

We aimed to assess the effect of water temperature on fish performance and the microbial communities of the system, and to describe the microbial communities present in the water, the fish gut, and the feed during the initial stages of larval rearing, after first feeding.

**Material and methods**

In a 47-day larval rearing experiment, we investigated the differences between two temperature regimes (16 °C vs. 20 °C) in two identical recirculated systems. The 500-litre tanks were used in triplicate, combined with high stocking densities (150 larvae/litre), and a 24-hour photoperiod. For the microbiological investigation, samples of water and fish larvae were collected in triplicates at three time points (24, 34 and 47 days post-hatch: T1, T2, and T3). After DNA extraction, we sent the samples to Edinburgh Genetics Limited for whole genome sequencing and metagenomic sequencing analysis. Data and statistical analysis were conducted using various diversity indices, PCoA, Bray-Curtis ANOSIM, and relative abundances of taxa. To assess larval performance, we measured growth parameters (body wet-weight, total length), survival rate, swim bladder inflation rate, and the occurrence of jaw and spine deformities. Statistical differences were evaluated ($p < 0.05$) using one-way ANOVA and Mann-Whitney U Test (SPSS 29.0, IBM Co., Armonk, NY, USA).

**Results and conclusion**

At 20 °C, the larvae performed significantly better in terms of final wet-weight, final total length, and swimbladder inflation rate compared to the 16 °C system. However, we found no significant differences regarding the survival and deformation rates.

We observed a temporal variation in water microbial community structure and composition. Regarding the two different temperatures (16 °C vs. 20 °C), no statistically significant differences were detected in either the water microbial community or the fish microbiome. In the rearing water, *Vibrio* sp. and *Pseudoalteromonas* sp. were the dominant pathogens at T1, but their abundance decreased at T2 and T3. At T2 and T3, the dominant pathogen was *Aeromonas* sp.

*(Continued on next page)*

In conclusion, higher rearing temperatures can enhance the growth and performance of pikeperch larvae without significant negative effects. Further investigations are required to address the non-significant, yet visible differences at 20 °C, such as higher deformity rates and a relatively higher abundance of *Vibrio* sp. in the larvae gut during the live feed period.

The European Fisheries Fund (EMFAF) and the Ministry of Agriculture and Environment from Mecklenburg-Western Pomerania funded this study as part of the project Fish pathogens from fish farms and waters of the Northeast German Lake District (project number MV-II. 12-LM-03).

# POLYMERIC AND EMULSION ADJUVANTS FOR *Streptococcus agalactiae* GHOST VACCINE IN NILE TILAPIA

Andra Corder[1*], Sarah Kharief[1], Juliette Ben Arous[1], Nicolas Versillé[2], Eakapol Wangkaghart[3]

[1] Seppic, Paris La Défense - 50 Boulevard National - 92257 La Garenne Colombes, France
[2] Seppic- 127 chemin de la Poudrerie - BP 90228 - 81105 Castres Cedex, France
[3] Department of Agricultural Technology, Maha Sarakham University - Khamriang Sub-District Kantarawichai District - Maha Sarakham 44150, Thailand
Andra.Corder@airliquide.com

**Introduction**:
*Streptococcus agalactiae* is a major threat in tilapia aquaculture. This study evaluated the safety and efficacy of a *S. agalactiae* ghost vaccine (SAGV) formulated with novel adjuvants, Montanide™ GEL 02 (polymer) and Montanide™ ISA 763B VG (emulsion).

**Materials and Methods**:
For safety, 10 fish/group (~50g) were injected intraperitoneally with 0.2 ml of: PBS (control), SAGV alone (1 x $10^7$ CFU/ml), SAGV with Montanide™ GEL 02, or Montanide™ ISA 763B VG. Fish were observed for one week for adverse effects and necropsied at 4 and 8 weeks post-vaccination to evaluate chronic side effects. For efficacy, 90 fish/group (~ 50g) were injected intraperitoneally with 0.2 ml of the same formulations. Serum bactericidal activity and anti-*S. agalactiae* IgM titers were measured weekly for two months. Eight weeks post-vaccination, 45 fish/group were challenged with virulent *S. agalactiae* (1 x $10^8$ CFU/ml). Dead fish were collected daily, and tissues were collected for bacteriological examination to confirm *S. agalactiae* as the cause of death.

**Results**:
Safety assessment showed limited oily vaccine residue in the Montanide™ ISA 763B VG group due to the deposit effect inherent to oily adjuvants that allows slow antigen release. No aqueous vaccine residue was observed in the Montanide™ GEL 02 group. Both adjuvants significantly enhanced IgM antibody titers from 2 to 8 weeks post-vaccination ($p < 0.01$). Montanide™ GEL 02 and Montanide™ ISA 763B VG significantly improved protection against *S. agalactiae* challenge compared to SAGV alone ($p < 0.05$), with survival rates of 93.33% and 88.89%, respectively.

**Conclusion**:
The aqueous adjuvant Montanide™ GEL 02 and the oily adjuvant Montanide™ ISA 763B VG, are safe and effective for injectable *S. agalactiae* ghost vaccines in tilapia. They enhance both the humoral immune response and protection against bacterial challenge.

# VERMI-TEA PRODUCTION FROM FISH WASTE: A SUSTAINABLE APPROACH TO NUTRIENT RECOVERY IN AQUAPONICS

Gourav Dhar Bhowmick*, Ahmad Faisal, Poonam Biswal, Debasruti Bhattacharya, Dillip Kumar Swain

Agricultural and Food Engineering Department
Indian Institute of Technology Kharagpur
West Bengal, India
*Email: gourav@agfe.iitkgp.ac.in

## Introduction

Aquaponics systems present a promising solution for sustainable food production by integrating aquaculture and hydroponics. However, managing nutrient cycling and waste reuse remains a critical challenge. One innovative solution involves the incorporation of a vermi-trio reactor that utilizes fish sludge and plant waste for nutrient recovery and ammonia removal. This study explores the development and integration of such a reactor into an aquaponics setup, emphasizing the conversion of system-derived organic waste into valuable biofertilizers—vermicompost, vermiwash, and vermi-tea superior to its conventional counterparts (i.e. vermicompost system etc.). This closed-loop approach not only optimizes resource use efficiency but also reduces environmental impact and the dependency on synthetic inputs, making aquaponics more sustainable and economically viable.

## Materials and methods

The vermi-trio reactor was conceptualized focusing on a vertically stacked tray design to conserve space and enhance process efficiency. The structure was fabricated using durable wooden trays, selected for their cost-effectiveness and structural stability. To improve resistance against decomposition during composting, each tray was coated with two layers of plastic-based paint. The reactor accommodates the efficient transformation of fish sludge and plant waste into biofertilizers through vermicomposting. To ensure optimal functioning, the system is operated under controlled conditions suitable for *Eisenia fetida*, the earthworm species used for decomposition. An automated sensor system monitors and regulates environmental conditions, maintaining a temperature of 25–30°C and relative humidity of 50–70%, which are critical for efficient microbial activity and earthworm performance.

## Results

A small scale earthen pot setup was used for producing vermicompost using fish sludge and plant waste from the aquaponics system. The resulting vermicompost was nutrient-rich, containing phosphorus (0.455%), organic carbon (21.74%), and manganese (494 ppm), exceeding the nutrient concentrations typically observed in traditional cow dung-based vermicompost, while maintaining comparable levels of nitrogen, potassium, iron, and magnesium. This demonstrates the fish sludge vermicomposting efficiency in nutrient recovery and its potential as a sustainable alternative for organic waste management in aquaponics. By facilitating the reuse of system-generated waste, the vermin-tea reactor can enhance nutrient availability for plants, mitigates ammonia accumulation, and reduces reliance on synthetic fertilizers. This closed-loop design promotes resource efficiency and environmental sustainability in soilless farming systems. Future research will focus on testing of vermi-tea reactor and optimizing nutrient recovery processes and assessing long-term impacts on both plant and fish productivity to evaluate the scalability and commercial viability of this technology across diverse agricultural contexts.

Fig. 1. Fabricated vermi-trio reactor for vermi-tea recovery from aquaponics waste.

# AQUATIC MOSS MATS AS ALTERNATIVE BIOFILTER MEDIA FOR AQUAPONICS

**Introduction**
Conventionally, inert media such as plastic, ceramic or zeolite are conventionally used for wastewater biofiltration. However, these media need activation by microorganisms, and differentiate essentially based on their surface/mass ratio since biofiltration entirely occurs at the surface biofilm. The use of biodegradable media may enhance the sustainability of the system, while avoiding generation of decomposition-related pollutants. In this respect, due to their surface extension, peculiar microbiota and structural resistance, aquatic mosses appear to be very good (and innovative) supports for biofilters.

**Materials and Methods**
In this study, we evaluated aquatic moss mats as alternative mats for the biofiltration of aquaculture or aquaponic effluents. Two moss species [1], *Taxiphyllum barbieri* and *Leptodictyum riparium,* were obtained in semi-axenic form (Green Greener srl Policoro, Italy) and tested for their contribution on N metabolism, by evaluating i) TAN, $NO_2$ and $NO_3$, ii) competition with hydroponic cultivation by comparative application, and iii) microbiota association by 16S rRNA metabarcoding. A direct comparison with a classic biofilter was performed in a complete RAS populated with Apulian naturalized [2] Nile tilapia (*Oreochromis niloticus*) obtained from Azienda Ittica Agricola Residence San Nazario srls (Lesina, Foggia, Italy).

**Results**
Due to their extraordinary surface extension, mosses performed very well in N metabolization without preliminary activation. Competition with plants grown in a hydroponic culture configuration was not significant, which may have positive aspects. Mosses microbiota was peculiar and did not favor parasites or pathogens. Therefore, for their structural resistance, aquatic mosses appeared a very good support for biofilters demonstrating equivalence in real conditions with inert media. However, the quantity of mosses required can be several times less than any competing media.

**Conclusions**
Aquatic moss biomasses showed to be valuable and efficient biofilter media applicable to aquaculture, hydroponics and aquaponics.

# EGG POWDER AS A FUNCTIONAL INGREDIENT: EXPLORING ITS ROLE AS A NATURAL AND ECONOMICAL CHOLESTEROL ALTERNATIVE FOR SUSTAINABLE SHRIMP AQUACULTURE FEED STRATEGIES

Diana*

VEOS GROUP
Akkerstraat 4/A
8750 Wingene (Belgium)
Email: alex.diana@veos.be

Cholesterol is an indispensable nutrient in crustacean aquaculture, particularly for species like the Pacific white shrimp (*Penaeus vannamei*), which lack the metabolic pathways for de novo synthesis. Historically, marine ingredients like fish meal, commonly included in shrimp feeds, provided adequate levels of cholesterol. However, the drive towards sustainable aquaculture practices necessitates reducing reliance on fish meal due to cost, availability, and environmental concerns. Replacing fish meal with alternative protein sources, primarily plant-based, often results in diets deficient in cholesterol, compromising shrimp growth, survival, and overall health. Consequently, supplementation with purified, synthetic cholesterol has become a standard practice to meet the established dietary requirements (ranging from 0.05% to 1.0% depending on species and life stage, with 0.05-0.5% often cited for *P. vannamei*). While effective, synthetic cholesterol represents a significant cost factor in feed formulation, prompting a search for more economical and natural alternatives.

This review evaluates the potential of whole egg powder as a multifunctional ingredient capable of replacing synthetic cholesterol in shrimp diets. Whole egg powder is a nutrient-dense ingredient that provides high-quality protein, essential amino acids, energy-rich lipids, vitamins, and vital phospholipids. Moreover, it's manufactured through a gentle spray drying process that guarantees quality and high digestibility of proteins and essential amino acids. Crucially, it is also a natural source of cholesterol. This inherent cholesterol concentration suggests that incorporating egg powder into shrimp feed formulations could significantly contribute to, or potentially fully satisfy, the shrimp's dietary cholesterol requirement, thereby reducing or eliminating the need for expensive synthetic supplementation. The primary driver for exploring egg powder as a cholesterol alternative is economics. Egg powder is generally reported to be a more affordable ingredient compared to both high-quality fish meal and purified cholesterol. Replacing synthetic cholesterol with the cholesterol naturally present in egg powder could lead to considerable savings in feed production costs, enhancing the economic viability of shrimp farming operations. Beyond cholesterol, egg powder offers additional nutritional benefits. It provides a balanced amino acid profile, although potentially lower in certain limiting amino acids like methionine, lysine, and arginine compared to premium fish meals, requiring careful formulation. Furthermore, egg powder is rich in phospholipids, particularly phosphatidylcholine (PC), which are known to be essential for larval and juvenile shrimp growth, survival, and stress resistance. The phospholipid requirement for penaeid shrimp is estimated to be between 1.2-1.5%, often met by adding lecithin sources. Egg powder can contribute significantly to meeting this requirement.

Based on its natural cholesterol content, affordability relative to synthetic cholesterol, and additional nutritional contributions (protein, phospholipids, bioactive compounds), egg powder shows significant potential as a cost-effective alternative for cholesterol supplementation in *P. vannamei* diets. Its use could alleviate the economic burden associated with purified cholesterol while contributing to overall shrimp nutrition and health. However, successful implementation requires formulation to balance its different nutrients. Further research, including dedicated feeding trials with *P. vannamei*, is ongoing, and it's crucial to determine the optimal inclusion levels of egg powder for effective cholesterol replacement, evaluate its impact on growth performance and health, and fully realise its potential as a sustainable and economical ingredient in shrimp aquaculture.

# *Bacillus subtilis* SPORES MODULATE ANTIVIRAL RESPONSES IN RAINBOW TROUT

## Introduction

In aquaculture, the use of probiotics in supplemented diets has been shown to be a suitable strategy to increase the immune status of fish and thereby reduce the impact of pathogens (Simón *et al.*, 2021). Specifically, the immunostimulatory effects of the probiotic microorganism *Bacillus subtilis* have been widely confirmed both *in vitro* and *in vivo* in many aquacultured species (Docando *et al.*, 2021; Vicente-Gil *et al.*, 2024). However, the potential effect of probiotic supplementation on antiviral capacities has been scarcely investigated in fish. Therefore, in this study, we aimed to address this gap using rainbow trout (*Oncorhynchus mykiss*) as a model species. Thus, fish were fed a diet supplemented with *B. subtilis* spores or a control diet during a long period (45 days) and the levels of transcription of a range of antiviral genes determined. In another experiment, after 30 days of feeding, spleen and head kidney leukocytes were isolated and exposed to two viral stimuli: Poly I:C - a synthetic analogue of double-stranded RNA (dsRNA) known to induce antiviral responses in rainbow trout cells (Simón et al., 2023) and heat-inactivated viral hemorrhagic septicemia virus (iVHSV). The levels of transcription of antiviral genes was then measured in these cells.

## Materials and methods

The basal diet used in all feeding trials was a commercial formulation (Skretting, Stavanger, Norway). To prepare the supplemented diet, lyophilized spores of the probiotic bacteria *B. subtilis* dissolved in 0.9% NaCl saline solution, were thoroughly mixed with the basal feed pellets. The spore concentration used was 1 x $10^{10}$ spores/kg of feed. Healthy rainbow trout (*Oncorhynchus mykiss*) were fed either the control or the enriched diet once a day at a rate of 2% body weight per day for 45 or 30 days, for the *in vivo* and the *ex vivo* trial, respectively. In the first experiment, fish were euthanized by benzocaine overdose (50 mg/ml) and spleen and head kidney collected. The tissues directly placed in TRI Reagent solution for RNA extraction. In the second experiment, kidney and spleen were collected from sampled fish for the isolation of total leukocyte populations. To this aim, tissues were mashed through a 100 µm nylon mesh and placed onto 30/51 % Percoll gradients, following the protocol described by Vicente-Gil *et al.* (2024). Total head kidney and splenic leukocytes were then diluted in L-15 supplemented with antibiotics (1% penicillin/streptomycin) and 2% fetal calf serum and seeded onto 24-well plates at concentrations of 4 x $10^6$ and 1 x $10^7$ cells/well, respectively. At this point, either 50 µg/ml of poly I:C or heat inactivated VHSV (iVHSV, 1 × $10^6$ $TCID_{50}$/ml) were added and leukocytes incubated at 19ºC. Untreated cells were also included as controls for each fish. After 24 h, RNA was extracted with TRI reagent. cDNA was synthesized from RNA samples from both experiments and used to assess antiviral gene expression levels by real-time PCR, using the $2^{-\Delta Ct}$ method, where ΔCt is determined by subtracting the β-*actin* value from the target cycle threshold. Negative controls with no template and *minus* reverse transcriptase controls were included in all cases.

*(Continued on next page)*

## Results

In the *in vivo* trial, we observed limited transcriptional changes in response to the supplemented diet in both the head kidney and spleen. Particularly in spleen, only the expression of *tlr22* and *lpg2b* genes were significantly increased in fish fed *B. subtilis* spore-supplemented diet compared to the control group. Similarly, in head kidney, the transcriptional factor STAT3, known to be involved in antiviral pathways, was the only upregulated gene in fish receiving the supplemented diet. Comparable results were obtained in head kidney leukocytes from fish fed either the control or the *B. subtilis*-supplemented diets, and subsequently exposed to PolyI:C and iVHSV, showing no major differences in gene expression levels. However, spleen leukocytes from fish that received the probiotic-supplemented diet, exhibited upregulation of nearly all antiviral related genes studied, including interferons 1 and 2, TLRs and *stat3* upon viral stimuli at levels higher to those elicited by the virus in leukocyte cultures from fish fed the control diet. These results highlight the importance of diet composition in regulating the capacity of leukocytes to respond to viral stimuli. Specifically, the *B. subtilis*-supplemented diet appears to prime leukocytes, particularly in the spleen, to mount a stronger antiviral response, suggesting a promising prophylactic strategy for use in aquaculture.

Summer survival has become an increasingly critical focus for salmonid producers, as climate change has heightened thermal stress, leading to reduced growth and increased mortality. Improving thermotolerance through selective breeding offers a promising strategy to protect animal welfare and commercial returns. However, selecting for thermotolerance remains challenging due to the variability of environmental conditions and the invasive nature of heat challenge tests.

This study reports genetic parameters and improvement strategies for thermotolerance in a multi-generational Chinook salmon (*Oncorhynchus tshawytscha*) breeding program, based on both laboratory challenge tests and summer cage survival data. A laboratory-based thermotolerance challenge was conducted across three year-classes. Individuals were exposed to progressively increasing temperatures (15°C to 23.5°C) and maintained at elevated temperatures for over two weeks in recirculating systems. Traits recorded included feeding behaviour, weight and length (pre- and post-challenge), and time to death (TTD).

TTD displayed moderate heritability ($h^2$ ~0.4) across all year-classes, supporting its utility for selection. Incorporating genomic predictions via a medium-density, sequencing-based platform increased Estimated Breeding Value (EBV) accuracy by ~10% compared to pedigree-based methods. Importantly, thermotolerance traits measured in the lab were moderately and consistently correlated with summer cage survival within the same year-class ($r \approx 0.3–0.5$), validating the relevance of the challenge test to real-world performance.

These results highlight the value of combining validated laboratory phenotypes with genomic selection to address complex traits like thermotolerance. Integrating challenge-test performance with field-based survival data enables cumulative genetic gains, enhances fish resilience under warming conditions, and strengthens the sustainability of salmonid aquaculture.

# EMERGING PHENOTYPING METHODS FOR FEED EFFICIENCY IN ATLANTIC SALMON: FROM INTAKE TO LIPID UTILIZATION

Difford, G.F.[1]*, Nicholas Jacob[1], Aqeel Ahmad[1], Jisoo Park[1], Tiril Aurora Lintvedt[2], Nils Kristian Afseth[2], Jens Petter Wold[2],Emmanuel Okoli Odah[1], Peer Berg[1], Gunnar Klemetsdal[1], Jørgen Ødegård[1,3], Hanne Dvergedal[1,3]

**Introduction**

Feed efficiency is a cornerstone of sustainable aquaculture, with the potential to reduce both production costs (Iversen et al., 2020) and environmental impact (Winther et al., 2020). However, direct phenotyping of individual feed intake and nutrient utilization in Atlantic salmon remains challenging at commercial breeding scales (de Verdal et al., 2017; Knap and Kause, 2018) so feed efficiency improvement is of great importance. Our aim is to use work done in pigs to formulate a logical framework for assessing the most useful component traits influencing feed intake and efficiency in farmed fish – either to identify traits that can together be used for genetic improvement of feed efficiency, or as substitute traits for feed intake recording. Improvement of gross feed efficiency in growing fish can be accomplished by selection for increased growth rate. However, the correlation of growth with feed efficiency is typically only modest, and hence there is room for further improvement of feed efficiency through methods other than growth selection. Based on a literature review we propose that the most effective additional methods are selection for reduced body lipid content and for reduced residual feed intake (RFI. To phenotype feed efficiency it is necessary to measure individual feed intake and calculate feed efficiency or identify traits in the bioenergetic pathway which contribute to variation in feed efficiency. King among bioenergetic traits are lipid deposition traits, lipid composition traits and their changes over time.

We present a suite of high-throughput, and scalable phenotyping methods aimed at capturing variation in feed intake, lipid metabolism, and overall feed efficiency across life stages. The objective of this study was to evaluate the feasibility, and genetic potential of these methods for phenotyping individual feed intake in Atlantic salmon.

**Materials and Methods**

We evaluated five novel phenotyping methods across ~2,000 Atlantic salmon from 23 full-sib families. Trials were conducted at the Norwegian Centre for Fish Trials (Ås, Norway) during the freshwater phase (50–100 g) and at Nofima's Centre for Recirculation in Aquaculture (Sunndalsøra, Norway) during the saltwater phase (500–2,000 g). On three separate occasions, fish were fed experimental diets containing 5% embedded metal micro-pellets and scanned using a calibrated metal detector.

During each trial, fish were fed to satiation in small family groups and scanned post-prandially using a semi-portable conveyor-based metal detector. At the third and final sampling, fish were euthanized humanely, gutted, and filleted. Feed intake was then confirmed through gut analysis using both metal detection and X-ray imaging. In parallel, tissue samples were collected for stable isotope and spectral analyses.

The data was analyzed with a linear mixed animal model using the DMU software (Madsen and Jensen, 2013), including fixed tank and sex, and a random additive genetic effect based on the genomic relationship matrix (G). Heritability ($h^2$) was estimated from variance components. The five phenotyping approaches evaluated were:

*(Continued on next page)*

Stable Isotope Analysis: $\delta^{13}C$ and $\delta^{115}N$ values were analyzed in fillet tissue to infer carbon and nitrogen assimilation as indicators of nutrient utilization and feed efficiency (Dvergedal et al., 2019, 2020). Family-level isotope ratios showed correlation with feed conversion ratio, providing a biochemical proxy trait for breeding. Metal Detector Scanning: A calibrated, conveyor-driven metal detector was used to non-invasively quantify individual feed intake based on postprandial field strength signals. The metal beadlets are Fish radio-opaque and were X-rayed post gutting to count markers in the gastrointestinal tract. Individual feed intake was estimated by calibrating marker count to feed weight (Difford et al., 2023; Ahmad et al., 2025b). Interactance Near-Infrared Spectroscopy (iNIR): Whole-body, fillet, and viscera NIR spectra were used to predict lipid content and feed intake through partial least-squares regression (PLSR) (Ahmad et al., 2025a). Raman Spectroscopy: Portable Raman probes were applied to fillets to assess fatty acid composition, focusing on omega-3 content (Lintvedt et al., 2022). This method is non-destructive and shows promise for high-throughput lipid phenotyping in breeding programs.

**Results**

Preliminary results from these trials will be presented. The study demonstrates the feasibility of several novel, non-invasive methods for phenotyping feed intake and efficiency in Atlantic salmon. While each method shows potential for application in selective breeding, differences in accuracy, heritability, and scalability were observed. These findings highlight both the promise and the current limitations of emerging phenotyping technologies, underscoring the need for continued research and development to improve their reliability, biological interpretation, and technology readiness level.

The expansion of aquaculture is essential to meet the food security of the growing human population, which requires optimizing the sustainable development of the sector. Microalgae are a sustainable resource and are essential for the initial stages of development of marine fish larvae, being applied in green water technique, rotifer cultivation and enrichment of live feeds. Currently, the required volumes of microalgae exceed the production capacity within nursery infrastructures, which, combined with the high challenges of their production, leads to a high demand for commercial microalgae products. Although rotifers production and enrichment are broadly used for many decades in aquaculture, their nutritional requirements and metabolism are still poorly understood which impairs the development of high-performance products for these purposes. Some of the great challenges of microalgae products for aquaculture are the design according to the specific needs of end users and the design of formulations adapted to the species, aquaculture production systems and production methods. Additionally, products must be developed considering the major current challenges in aquaculture, such as the incidence of pathologies, water quality control and reduction of waste accumulation (product sedimentation). To solve the mentioned issues, Necton has developed 5 new sustainable microalgae-based products with added-value to fill these gaps. This work reviews the strategies of new microalgae products development to address the current challenges in marine fish nurseries production. Three products were developed in the new VitaBloom® product range, that combine microalgae and probiotics in powder for green water technique (Green water), rotifers nutrition (Rotifers+) and live feed enrichment (Enrich). Green water product is adapted for green water technique in open systems, Rotifers+ is developed for semi-continuous and batch rotifers production and Enrich is adapted for rotifers and artemia enrichment. Two new Premium *Nannochloropsis* sp. liquid concentrates were developed with low bacterial content and low microalgae agglomeration, adapted to different cultivation methods. PhytoBloom® ELITE formula (ELITEf) was developed for rotifers batch cultivation and PhytoBloom® RAS formula (RASf) was specifically designed for rotifers cultivation in the challenging Recirculation Aquaculture Systems (RAS) with semi-continuous production, and for green water technique. VitaBloom® range was obtained through the combination of different species of microalgae and yeast, to fulfil the nutritional requirements of rotifers and fish larvae and validated *in vivo* in rotifers and fish larvae cultivation (*Sparus aurata* and *Argyrosomus regius*). Premium PhytoBloom® *Nannochloropsis* sp. were formulated for rotifers cultivation since this species demonstrates high rotifers production and is a highly demanded product for their cultivation due to liquid concentrates easy application. Mitigation of the incidence of pathologies was addressed through two different strategies, namely the use of probiotics (VitaBloom®) or reduction of product bacterial load (PhytoBloom® premium products). Probiotics are known to inhibit *Vibrionaceae*, which include several of the most prevalent pathogens responsible for mortalities, and have beneficial effects on the biological performance of the organisms and higher resistance to stress[1]. The reduction bacterial load of the products improves the water quality and avoids the proliferation of potential pathogenic bacteria[2], and is particularly useful for the cultivation of species highly susceptible to the presence of bacteria in the water.

*(Continued on next page)*

The reduction of microalgae agglomeration was tackled in all products through the optimization of the formulations processing technologies to reduce sedimentation and the formation of microalgae agglomerates in the water, which is a major constraint since it promotes product sedimentation, debris formation, reduction of water quality and the organism's biological performance. In liquid concentrates, the ionic composition of salt solutions and their salinity was optimized to reduce microalgae agglomeration since *Nannochloropsis* sp. cell wall has a negative charge that influences the interaction with other molecules and particles[3]. Thus, the ionic strength was modulated through different salt solutions to reduce *Nannochloropsis* sp. agglomeration in the water column and improve the product suspension in water. In Rotifers+ an ammonia chelating water conditioner was used in order to reduce the concentration of this metabolite that is toxic to rotifers[4], as it is responsible for inhibiting reproduction and crashing the rotifer population, particularly in the challenging semi-continuous production. The reduction of the number and size of the particles in the water column can promote the reduction of the microalgae sedimentation, thus improving particle suspension on the water column, increasing feed availability of microalgae for rotifers nutrition, reduces waste formation, bacteria proliferation, oxygen consumption and toxic ammonia accumulation in the tanks.

In *A. regius*, Green water product increased 36% larvae survival post transport stress challenge and reduced 108% malformations affecting phenotype compared to green water technique with live *Nannochloropsis* sp. Rotifers+ increased 64% rotifers production in batch and 92% rotifers production in semi-continuous production. Enrich showed 20% more in *S. aurata* survival post-weaning, adequate biochemical profile of enriched rotifers and artemia for *S. aurata* nutritional requirements and a reduction of stress enzymes post transport stress challenge. ELITEf allowed to increase batch rotifers production by at least more 50% than a commercial product and RASf enhanced rotifers production in RotiRAS system at least 50% compared to a commercial product. Moreover, RASf reduced the maintenance of the system since it does not promote the filters clogging of the system and have a reduced debris accumulation in the tanks.

In conclusion, the appropriate design of the formulas of specialized microalgae products made it possible to respect the technical needs of the organisms and aquaculture systems, reducing the effort of human resources, simplifying the daily procedures in the nursery, obtaining higher biological performance of the organisms and a high cost-benefit relation of the product application. All these characteristics are essential to leverage aquaculture profits and sustainable production growth.

## Introduction

Climate change has been altering the Earth's climatic system, including rising sea temperatures, ocean acidification, extreme weather events, and biodiversity loss[1]. These changes threaten both wild and cultured species[2,3]. *Mytilus galloprovincialis*, one of Europe's most important farmed mollusk species, is primarily cultured on rafts in the nutrient-rich rías—drowned river valleys—of Galicia, on Spain's northwest coast[4]. Due to their filter-feeding lifestyle, mussels constantly face environmental stress and rely on their innate immune system to cope with these challenges. Additionally, mussel attachment to substrate (rocks and culture ropes) depends on the structure of the byssus. Together, immune function and byssus strength are critical for mussel survival. In this study, we investigated how the spatial (raft location) and temporal (seasonality) parameters affect the immune response and byssus production of cultured mussels.

## Materials and Methods

Four rafts were selected in the Ría de Arousa, which hosts 60% of Galicia's mussel rafts: two highly exposed to waves (OuN and OuS), one in sheltered inner areas (InC), and one in the middle section (MidW) with intermediate conditions (Fig. 1A). Six mussels (three at 0-6 m and three at 6-12 m depth) were sampled per raft/season (spring, summer, autumn, winter), then transferred to aquarium facilities for processing (Fig. 1B). To assess the mussels' cellular stress response, the activity of reactive oxygen species (ROS) and nitric oxide (NO) was measured via chemiluminescence and spectrophotometry, respectively. Gene expression related to oxidative stress, immunity, and thermal stress (GST, LYS, HSP70) was also analyzed in gills using qPCR. Byssus production was evaluated through Mgfp3 gene expression to infer the risks of biomass maintenance in the rafts.

## Results and Discussion

Factorial ANOVA revealed that seasonality had the largest effect on all response variables. Raft position ranked as the second most influential factor in the case of NO production and the expression of immune genes. No significant differences were noted for rope depth in any variable. ROS and NO levels were higher in the summer, which appears to be an oxidative stress response to increased metabolism and pathogen pressures resulting from higher temperatures (Fig. 2). The expression of immune genes also varied seasonally, reflecting a targeted seasonal pattern based on food availability, spawning events, pathogen load, and thermal stress (Figs. 3A, B, C). Byssus production peaked in the spring, likely due to favorable conditions for attachment, allowing the mussels to invest more energy in byssus reinforcement to cope with the seasonal changes. It was, however, reduced in summer as mussels probably prioritize stress management (Fig. 3D).

## Conclusions

Despite mussels' range of tolerance, this study highlights the complex relationship between environmental stressors, such as pathogens and weather conditions, and mussel performance. It emphasizes the importance of implementing sustainable aquaculture practices to optimize health and attachment strength while minimizing stress during critical periods. Understanding these dynamics is crucial for adapting mussel farming strategies to the challenges posed by climate change, ensuring the resilience of this vital species.

# MOLECULAR RESPONSE OF THE MEDITERRANEAN MUSSEL TO CONTAMINANT GRADIENTS IN THE GALICIAN COASTAL RÍAS

Sonia Dios*, Mónica Calvo, Camino Gestal, María M. Costa, Antonio Cobelo-García

Instituto de Investigaciones Marinas (IIM), CSIC
Eduardo Cabello 6
36208, Vigo, Spain
E-mail: sdios@iim.csic.es

## Introduction

The Galician coastline is characterized by a system of drowned river valleys, known as rías, which benefit from nutrient-rich upwelling waters and support extensive aquaculture activities[1]. The Mediterranean mussel, *Mytilus galloprovincialis*, is the most widely cultivated mollusk in Galicia, with a 2022 production of ~200,000 tons, valued at €164 million (FAO)[2]. This makes mussel aquaculture a vital socioeconomic activity in Galicia. However, many of these coastal areas are located near densely populated zones, receiving significant anthropogenic pressure. To ensure the sustainability of this sector, it is essential to monitor the impact of emerging contaminants and pathogens that may affect both human health and aquaculture productivity. This study integrates field sampling and laboratory analyses to assess the molecular responses of mussels to environmental stressors.

## Materials and Methods

Seasonal mussel sampling (winter, spring, summer, autumn) was conducted in 2022/23 at three Ría de Vigo sites along a contamination gradient: Samil (low), Teis (moderate), and Cangas (high). RNA was extracted from the gills and digestive glands of 10 individuals per site and season. Gene expression of stress- and immune-related markers (GST, GPX, CAT, HSP70, C1q, and LYS) was analyzed using quantitative PCR (qPCR). Histological evaluation was performed using paraffin embedding and hematoxylin-eosin staining. Additionally, 1 L of seawater per site and season was filtered (0.22 $\mu$m) and analyzed by specific nested PCR C-D for the detection of Ostreid herpesvirus 1 microvariant (OsHV-1 $\mu$Var)[3].

## Results and Discussion

Gene expression analysis revealed site-specific patterns in gill tissue (Fig. 1A). Mussels from Teis exhibited the highest expression levels for HSP70 (53.96%), GPX (48.45%), and GST (43.65%), suggesting a strong oxidative stress response. In contrast, Samil showed a marked increase in LYS (65.42%), potentially reflecting localized immune activation. Seasonal variation in gene expression was also evident (Fig. 1B). Mussels sampled in summer and autumn exhibited elevated levels of HSP70, GST, and GPX, indicating increased environmental stress during warmer months. In contrast, winter samples showed consistently lower expression across all genes, while spring samples revealed moderate activation, suggesting transitional physiological responses. Gene expression in the digestive gland also varied significantly among sites (Fig. 1C). Mussels from Samil exhibited the highest expression levels for most of the genes, including GST (71.20%), GPX (67.71%), and LYS (62.38%), indicating a robust oxidative stress response and immune activation in this location. Conversely, mussels from Teis exhibited elevated levels of C1q (53.07%) and HSP70 (28.70%), suggesting that different stressors or environmental conditions influenced these markers. Seasonal variation in gene expression within the digestive gland also exhibited distinct patterns (Fig. 1D), mirroring those in the gills. Although histological analyses are still in progress, preliminary findings suggest that there are no detectable tissue alterations across sampling sites or seasons. OsHV-1 $\mu$Var (Fig. 2) was most frequently detected in Cangas during autumn, showing the highest viral load. Additional detections occurred in Teis and Samil during summer, in Cangas during winter and spring, and in Samil during spring. No viral DNA was detected in Teis during autumn and winter, nor in Samil during winter. These results suggest a stronger and more persistent viral presence in the most contaminated area (Cangas), with sporadic detection in moderately (Teis) and minimally (Samil) impacted sites.

## Conclusions

This study demonstrates the effectiveness of integrating molecular, histological, and environmental virological tools to assess mussel health across different contamination scenarios. The strong seasonal and spatial variability in gene expression suggests that mussels are sensitive bioindicators of environmental quality. The detection of OsHV-1 $\mu$Var in multiple locations and seasons highlights the circulation of this pathogen in Galician waters, which may pose a latent threat to aquaculture operations. The qPCR panel used proved to be a reliable tool for early detection of sublethal stress responses. When combined with histopathology and environmental pathogen screening, this approach can support the implementation of monitoring programs in bivalve production areas.

## Introduction and background

Aquaculture is pivotal in ensuring food security and nutrient supply to the world's growing population.

The developments of the past decades, which led to farmed production surpassing capture fisheries in 2022 (SOFIA, 2024), have brought to light several challenges related to the sector's sustainable development.

Among the most discussed issues is the need for diets that reduce dependency on raw materials directly "extracted" from nature, such as fishmeal and fish oil. Although plant-based ingredients have helped lower the trophic level of farmed species (Cottrell et al., 2021), adverse effects on fish health and growth, mainly due to anti-nutritional factors and nutrient imbalances, have been demonstrated (Krogdahl et al., 2010). Furthermore, their use has intensified competition for resources needed for direct human consumption and land and water usage (van Riel et al., 2023).

In the European context, where the Green Deal pursuits the ambitious goal of a climate-neutral continent by 2050, and specifically its core "Farm to Fork" strategy, which promotes a healthy, resilient, and transparent agri-food system, have significantly influenced current developments in the livestock and aquaculture sectors. In this regard, circular solutions such as the use of Processed Animal Proteins (PAPs) have attracted considerable interest, as they provide nutrient-rich ingredients, recover raw materials, and offer a local source of protein for animal feed, thereby reducing dependency on imported nutritional sources.

Consumers, who often lack detailed knowledge regarding the feeding practices of farmed animals (Popoff et al., 2017), play a crucial role in adopting these practices, as they are the end users of food products that embody all upstream decisions made along the supply chain. While recent studies on consumer acceptance of PAPs in aquafeeds have mainly focused on insect-derived sources, limited attention has been given to those obtained from poultry and pigs. Against this backdrop, the present study aims to investigate the variables and perceptions that influence the acceptance of such practices among consumers residing in Italy.

## Methodology

The survey was conducted through a questionnaire administered using the CAWI method (Computer-Assisted Web Interviewing).

The questionnaire, divided into different sections and developed based on previous studies on the topic, was designed to qualitatively and quantitatively identify the factors influencing the perception and potential consumption of fish fed with PAPs derived from insects, poultry, and pigs. The included questions were selected to assess sociodemographic characteristics, subjective and objective knowledge, and consumption habits.

One of the strengths of this study is the use of a significant number of respondents, selected through stratified sampling based on population and gender, according to data provided by the Italian National Institute of Statistics. This approach aims to generalize findings to the broader national context regarding consumer perception.

*(Continued on next page)*

## Results

The results of this research will be compared with the existing literature, specifically with the findings from a previous study conducted by the authors (Dolfi et al., 2025 in press).

While Italian consumers have generally shown a low willingness to pay for fish fed with insect meal, the present study aims to compare different diets composition to understand consumer perceptions toward different circular practices.

Moreover, given the limited interest previously reported by consumers regarding sustainable farming practices, this study will also provide detailed insights into the reasons behind this attitude.

## Acknowledgements

**Introduction**
Agriculture and terrestrial livestock have long been key sources of protein, but they are also associated with significant environmental impacts, including nutrient pollution and greenhouse gas emissions (Ilea, 2009). In contrast, bivalve aquaculture offers a more sustainable protein production system, requiring no feed inputs and delivering valuable ecosystem services such as nutrient remediation and carbon sequestration (Higgins et al., 2011 and Van der Schatte et al., 2020). This study aims to evaluate the environmental performance of Irish Pacific oyster farming by combining life cycle assessment (LCA) with ecosystem service analysis to understand better its role in reducing eutrophication and mitigating climate change.

**Materials and methods**
This study assessed ecosystem services and environmental impacts of Pacific oyster farming in Ireland using both field sampling and LCA methodology. Morphological and elemental analyses were undertaken on oysters from two production sites, measuring carbon (C), nitrogen (N), and phosphorus (P) content in both tissue and shell. These values were extrapolated to farm and national levels to estimate annual nutrient removal and assign economic value to this ecosystem service. LCA was performed on three sites using primary farm data and secondary databases, covering activities from seed procurement to processing. Environmental impacts were quantified using the CML method, and nutrient and carbon sequestration in oyster shells were integrated into the LCA results to calculate net eutrophication and greenhouse gas emissions.

**Results**
The study found that Pacific oyster farming in Ireland provides significant ecosystem services, removing an estimated 834.3 tonnes of carbon, 33.9 tonnes of nitrogen, and 3.9 tonnes of phosphorus from coastal waters annually. The LCA results showed a carbon footprint of 373.86 kg $CO_2$-eq per tonne of oysters, primarily driven by electricity use and diesel combustion. On the other hand, results showed a eutrophication potential and acidification potential of 0.39 kg $PO_4$ eq. tonne$^{-1}$ and 1.33 kg $SO_2$ eq. tonne$^{-1}$, respectively. Using ecosystem services metrics, one tonne of harvested oysters can remove, on average, 3.05 kg of nitrogen, 0.35 kg of phosphorus, and sequester 70.52 kg of carbon from the environment, thus potentially acting as a nutrient remediator and a short-term carbon sink. From an economic perspective, the valorisation of the nutrient removal potential resulted in an additional income of €1.9 million per year to the Pacific oyster industry, of which N removal accounts for 97.67%.

**Discussion**
This study provides a comprehensive evaluation of Ireland's Pacific oyster farming sector, focusing on its contributions to ecosystem services and environmental impacts through a life cycle assessment. While oyster farming demonstrated lower environmental impacts than other protein production systems (Aubin et al., 2009; Nguyen et al., 2010; Djekic et al., 2015; Kalhor et al., 2016), challenges remain in assessing nutrient and carbon fluxes due to methodological limitations. The study highlighted the role of biodeposition and denitrification in nutrient cycling (Ayvazian et al., 2021) and stressed the need for improved LCA models to capture these services more accurately. Extrapolations were made under justified assumptions, though future research is needed to account for regional variability. Economically, the Irish oyster industry could benefit from nutrient credit schemes and opportunities within the circular economy, such as reusing shells in agriculture and construction. The findings support the integration of oyster farming into environmental management strategies, including carbon farming and water quality improvement, and advocate for the expansion of environmental footprint assessments to inform sustainable aquaculture policy and practice.

## Introduction

Fish closely interact with their environment and the microorganisms that inhabit it. Accordingly, increasing attention is being given to the interplay between microbiota, host, and environment. While most studies focus on intestinal bacteria, other microbial niches—such as the skin and the surrounding water—are gaining importance as less or non-invasive biomarkers for monitoring fish health and welfare. There is now evidence that certain behavioural patterns can be modulated by targeting the gut microbiota (Olorocisimo et al., 2023). The relationship between the skin microbiota and specific behaviours has been less studied, although correlation analyses have also supported an association between skin microbiota and reactive or proactive behaviour in gilthead sea bream (*Sparus aurata*) reared at high stocking densities (Toxqui-Rodriguez et al., 2024). To further explore this line of research, the present study aims to characterize how seawater microbial dynamics influence and interact with the skin and rearing water microbiomes throughout the production cycle of gilthead sea bream. Moreover, by understanding the interactions among these three interconnected microbiomes, we explore the potential of using rearing water microbiota as a non-invasive proxy for monitoring host-associated microbial shifts in fish fed different diets formulations.

## Methods

Gilthead seabream juveniles were reared under natural photoperiod and temperature conditions (40°5'N; 0°10'E) at IATS facilities in an open-flow system. During the trial, fish were fed with a CTRL fish meal-based diet, or alternative feeds with processed animal protein (PAP), or insect meal + bacterial protein (ALT) as main novel fish meal replacers. Fish skin and rearing tank water microbiome were sampled at four time points: t0-May (13.2g); t1-July (70.3g); t2-November (295.9g); and t3-February (357.5g). At each sampling point, 9-12 fish per diet were sampled for skin mucus, and water samples were filtered (0.22 µm) to collect bacterial biomass. In parallel, to study seasonal fluctuations in the inlet seawater of the system, water samples were collected monthly during a two-year period from the inlet pipe (Jan-2023 to Dec-2024). After DNA extraction, full-length 16S rRNA (V1–V9) was amplified and sequenced using Oxford Nanopore (PromethION P2). Reads were basecalled (Dorado v0.9, SUP), and taxonomic assignment was performed with minimap2 using SILVA v138.2 as reference database.

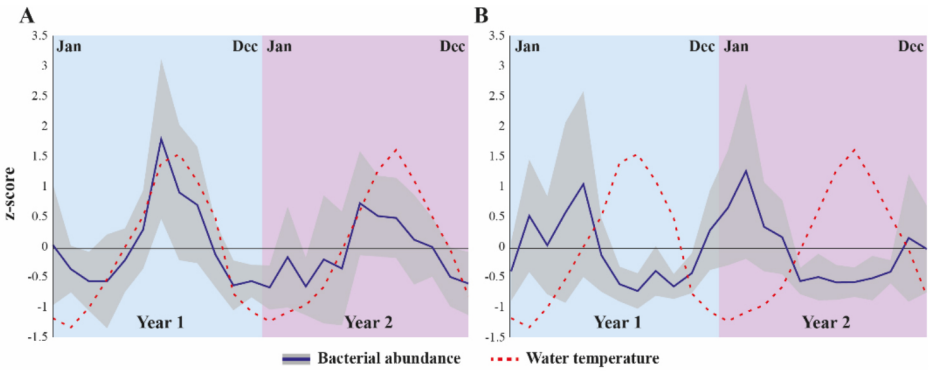

**Figure 1**. Bacterial abundance distribution of bacterial taxa with 12-month period with their peaks of abundance in winter (A) and summer seasons (B).

*(Continued on next page)*

**Results and discussion**

Microbiome composition of inlet and rearing water showed a dominance of three main phyla: Pseudomonadota, Bacteroidota, and Cyanobacteria. Similarly, the skin microbiota maintains the dominance of the first two phyla, while the presence of Cyanobacteria was significantly lower, being replaced by the Bacillota phylum. In terms of OTU prevalence, 130 taxa at genus level were shared consistently between water and the skin mucus. Interestingly, the abundances of 94 taxa (approximately 70% of the total shared microbiota) were positively or negatively correlated between skin and rearing water microbiomes. To refine this set of bacteria selected across time, we applied a time series analysis (RAIN analysis; Coenen et al., 2020) to seawater inlet samples collected across two consecutive years. As a result, among a list of 102 genera ($p < 0.01$) whose abundances were positively (Figure 1A) or negatively (Figure 1B) correlated with seawater temperature, 24 taxa exhibited the same seasonal variation in the skin mucus and rearing water microbiomes. These bacteria (representing 21.1 and 16.8% of the total water and skin abundance) are relevant because apart of being consistent in our facilities environment, can be measured in the rearing water as a non-invasive proxy of a host-associate microbiome.

In addition to time, beta-diversity analysis of skin microbiome revealed that diet represented the secondary source of variation. In fact, even with lower influence compared to temporal variable, LEfSe analysis identified 11 bacterial biomarkers associated with the diet including *Alteromonas, Cobetia* and various members of Paracoccaceae family. Notably, *Alteromonas*—the most abundant diet-discriminant genus—has previously been associated with a reactive behaviour in fish under high-stocking densities (Toxqui-Rodriguez et al., 2024). Interestingly, the ALT diet, enriched in this genus, has also been associated with this behavioural trait, reinforcing a possible link between diet, behaviour, and the skin microbiome.

**Concluding remarks**

This work reveals the cross-talk between the microbiomes of rearing water and fish skin mucus, supporting the potential use of rearing water microbiota as a practical, non-invasive tool for monitoring host-associated microbial shifts. These results reinforce the idea that water microbiome analysis can complement fish health monitoring strategies, offering a non-invasive approach to track broad microbial fluctuations within aquaculture environments.

**Introduction**
The study explores the use of calcifediol, a metabolite of vitamin $D_3$, as a dietary supplement in gilthead seabream (*Sparus aurata*). Vitamin D is an essential fat-soluble vitamin that fish are unable to synthesize and so require absorbing it directly from the diet (Lock et al., 2010). While vitamin $D_3$ is commonly used in aquaculture, its metabolite, calcifediol, has shown promise in livestock and rainbow trout (*Oncorhynchus mykiss*) (Atencio et al., 2005; Rider et al., 2023), but remains untested in marine species like seabream. Given the essential role of vitamin D in calcium homeostasis, bone development, and nutrient absorption (Lock et a., 2010; Sivagurunathan et al., 2022), this research aims to evaluate the effects of calcifediol on growth, biochemical composition, skeletal anomalies, and intestinal histology in seabream juveniles.

**Materials and Methods**
A total of 600 seabream juveniles (12.8 ± 1.5 g) were divided into five dietary groups with increasing levels of calcifediol: <2.0 (control), 99.7, 167.4, 298.6, and 825.4 ppb. All diets included 3000 IU/kg of vitamin $D_3$. The fish were reared for 15 weeks under controlled conditions and fed three times daily. Parameters measured included growth performance, feed conversion ratio (FCR), specific growth rate (SGR), biochemical composition, vitamin and mineral content, skeletal anomalies (via X-ray), and intestinal histology among others. Statistical analyses included ANOVA and regression models to determine significance ($p<0.05$).

**Results**
-*Growth Performance*: Fish fed 99.7 ppb calcifediol showed the highest growth and best FCR. Higher doses (298.6 and 825.4 ppb) reduced growth, suggesting potential toxicity.

-*Biochemical Composition*: Whole-body lipid content increased with calcifediol, while protein content decreased. Liver lipid levels rose linearly with supplementation. The whole-body omega 3/ omega 6 ratios describe a higher deposition of DHA and omega 3 in the diet containing 99.7 ppb of calcifediol, whereas the contrary was observed for fish fed the highest level of calcifediol.

-*Vitamin and Mineral Content*: Whole-body vitamin $D_3$ and vertebral calcium increased significantly at 99.7 and 167.4 ppb. Excess supplementation reduced calcium retention.

-*Skeletal Anomalies*: No significant differences were observed among groups.

-*Histology*: Mid-intestine fold length and goblet cell density improved at 99.7–167.4 ppb. Lamina propria width was thinner in supplemented groups, indicating better gut health.

**Discussion**
Calcifediol supplementation at 99.7 ppb significantly enhanced growth, nutrient retention, and intestinal morphology, outperforming traditional vitamin $D_3$. However, higher doses led to reduced growth and calcium retention, indicating a narrow safety margin. The findings align with previous studies showing vitamin $D_3$ toxicity at high levels in seabream (Sivagurunathan et al., 2022). The improved omega-3/omega-6 ratio and DHA deposition at optimal calcifediol levels suggest enhanced lipid metabolism. Histological improvements, such as increased goblet cells and reduced lamina propria width, support better gut health and nutrient absorption.

**Conclusions**

Calcifediol is a potent and efficient vitamin D source for gilthead seabream juveniles. A supplementation level of 99.7 ppb optimizes growth, feed efficiency, vitamin $D_3$ retention, and intestinal health. However, excessive levels (>298.6 ppb) may induce toxicity, reducing performance and mineral retention. These results highlight the importance of precise dosing when using calcifediol in aquaculture diets.

# EPIDEMIOLOGICAL SURVEILLANCE OF VIRUS OF RISK IN AQUACULTURE: BEYOND KNOWN VIRUSES

Emma González-Rosales, Mafalda González-Sequeiros, Sandra Souto, José G. Olveira, Isabel Bandín, Carlos P. Dopazo

Aquatic One Health Research Center
University of Santiago de Compostela
Spain
e-mail: carlos.pereira@usc.es

## Introduction

Taking advantage of metagenomics and metatranscriptomics tools, epidemiological studies of human viruses have evolved greatly in recent years. In aquaculture virology, we are a little behind the times, but progress is unstoppable. Epidemiological studies in aquaculture have been carried out for half a century, but the available tools, of the target type, only allowed us to detect those viruses that we already knew about in each geographical area. Nowadays, the availability of this other type of techniques allows us to carry out generic monitoring studies, looking for any type of known and unknown virus present. Preliminary results obtained in a study carried out in Ría de Arousa (NW Spain) show that this technology is useful for understanding the situation of natural and farmed populations, and support the defence of maintaining a permanent system for monitoring the spatio-temporal distribution of viruses in certain marine populations of interest.

## Materials and methods

Samplings were carried out in 5 coastal locations (Fig 1) (4 in Ría de Arousa and one, as a reference, in a nearby estuary), one in an internal area of the estuary, closer to river mouths and towns, 2 in a middle area, with added influence of fish farms, and one closer to open sea. In each case, water (20 L), sediment (1 Kg) and molluscs were sampled at two points, one in an unaffected production area and the other in an area of low or no production. In the present work, preliminary results are shown for sediment and water from two of these areas, one internal and one external.

The viruses were concentrated by reverse capillary osmosis filter systems, followed by ultracentrifugation. For detection of viral RNA sequences, after total RNA extraction and purification, the cDNA molecules library was constructed using a ribosomal depletion preparation kit, and the sequencing carried out in a Illumina Novaseq platform, using 150bp paired-end. For viral DNA sequencing, after extraction and purification of DNA, the library was contructed by the Kapa HyperPrep kit, and sequencing performed in a Illumina Novaseq platform as indicated.

## Results

Although only sequences with E values between 1 $e^{-21}$ and 0, and pairwise identity percentage over 80% were considered, metagenomics led to the discovery of hundreds of contigs with homology to sequences of particular interest in the aquatic environment: algae and microalgae viruses and plankton viruses, e.g., were very abundant. However, as an objective of the project was to determine the presence of viruses that could pose a risk to aquatic animals of interest in aquaculture, Table 1 only presents those viruses that could represent a certain risk to—or at least to have a certain relationship with—aquaculture. We did not observe a clear relationship between presence/absence of risk viruses and the type of coastal area (with or without productivity problems). Instead, we did detect relationship of the degree of virus diversity and the number of contigs for each virus with the location of the areas (clearly higher at the inner sampling points in the estuary).

We have highlighted in the table, using colours, those viruses that are published as posing a proven risk to the species indicated (red boxes) and those for which there is no clear data in this regard (yellow boxes). We also would like to highlight the possible presence of high-risk viruses for molluscs (e.g. pinnea, mussel or octopus) and crustaceans (crabs, prawns and others). Also noteworthy is the large number of contigs (more than 40) of betnodavirus, a virus that poses a risk to fish farming, especially Senegalese sole betanodavirus (31 contigs), which has a proven risk for that species, which is of high interest to fish farming in this area.

*(Continued on next page)*

Table 1.- Viral sequences corresponding to aquaculture risk viruses detected by metagenomics in water and sediments sampled in 2 coastal locations at the Arousa estuary.

| **Host** | | **Virus type** | |
|---|---|---|---|
| Bivalve molluscs | Mussels | Rhabdovirus | Chemarfal virus 1 |
| | | Densovirus | Clidnapec virus |
| | Other | Picorna-like | Beihai picorna-like virus strain 32 |
| | | Circovirus | Circovirus-like SAR-B |
| Other | Octopus | Picorna-like | Beihai picorna-like virus strain 32 |
| Crustacea | Crabs | Picorna-like | Beihai picorna-like virus strain 32 |
| | Prawn | Iridovirus | Acetes erythraeus iridovirus |
| | | Nimavirus | White Spot Syndrom Virus |
| | Other | Circovirus | Circovirus-like SAR-B |
| Echinoderm | Sea star spp | Densovirus | Asterias forbesi-assoc. densov. |
| | | Circovirus | Starfish wasting disease |
| Fish | Salmonids | Orthoreovirus | Piscine Orthoreovirus |
| | Senegalese sole | Betanodavirus | Recombinant NNV |
| | Gilthead sea bream | Betanodavirus | Recombinant NNV |
| | Pearl gentian grouper | Betanodavirus | RGNNV |
| | Redspot grouper | Betanodavirus | RGNNV |
| | Tiger grouper | Betanodavirus | RGNNV |

**Discussion and Conclusions**

The preliminary results of this study demonstrate, first, that there could be more viruses posing a risk to aquaculture in the study areas than are currently known in this region and, second, that the potential risk is greater in the innermost areas of the estuary. However, the presence of the sequences detected in metagenomics, although reliable (due to the restrictive criteria used), is not sufficient to demonstrate the presence of those viruses. Therefore, primer/probe sets are currently being selected to apply real-time PCR and digital PCR to demonstrate or rule out their presence.

# DEVELOPMENT AND NUTRITIONAL EVALUATION OF AN ARTISANAL CANNED AMAZONIAN SILVER CROAKER (*Plagioscion squamosissimus*): ADDING VALUE TO THE REGIONAL FISH SUPPLY CHAIN

A J S Dias*, L V S Santos, N P B Façanha, G A Silva

*Laboratory of Organic Chemistry and Biochemistry
State University of Amapá
Macapá, Amapá, Brasil
Email: arllon0006@gmail.com

**Introduction**

Fish is considered a privileged meat product from a nutritional point of view, as it is rich in polyunsaturated fatty acids (especially omega 3), has high-quality protein, digestibility, biological value, and is also a source of vitamins and minerals (Dias and Silva, 2021). In the Amazon region, fishing is considered the basis of the economy of some cities and traditional communities, which stands out for the wealth of fish that are exploited and the quantity of fish and shrimp caught annually.

With this in mind, we considered technologies related to value-added preserves (new cuts, new sauces, new ingredients) developed from fish, intended for human consumption and nutrition. Therefore, fish is the main food source in the Amazon region and according to FAO data indicating that this same consumption tends to increase on a national and global scale, this work aimed to develop an artisanal preserve made from silver croaker (*Plagioscion squamosissimus*) in tomato sauce and to characterize this product proximally.

**Material and methods**

The fish were purchased at a street market in the municipality of Macapá, state of Amapá, Eastern Amazon, through donations. The fish were inspected and then scaled, their heads, viscera and fins removed, and the parts separated for canning.

Then, the parts intended for canning were immersed in hyperchlorinated water in accordance with industrialization and quality control standards. The fish were cleaned, processed (special cuts) and placed in glass jars, and the topping sauce was then added, and the jars were then covered and subjected to the cooking process. The jars containing the ingredients underwent heat treatment (cooking) for 50 minutes, and the pressure reduction should be allowed to drop for 10 minutes before opening the pot, to prevent the lids from bulging. After removing the jars from the pressure cooker, they were allowed to wait until the internal boiling of the glass ended and then they were inverted until they cooled.

After preparing the preserves, moisture, ash, total lipids and total proteins were determined according to the methodologies proposed by official analysis methods (AOAC, 1990), carbohydrates and caloric value as described by Dias and Silva (2021). The centesimal composition analyses were performed by groups of triplicates.

**Table 1.** Proximate composition of artisanal Amazonian silver croaker (*Plagioscion squamosissimus*) in tomato sauce, preserved in a glass jar.

| Parameter | Silver Croaker *(Plagioscion squamosissimus)* |
|---|---|
| **Humidity (g/100g)** | 82.46 ± 2.02 |
| **Mineral waste (g/100g)** | 0.23 ± 0.26 |
| **Total lipids (g/100g)** | 2.32 ± 0.15 |
| **Total proteins (g/100g)** | 12.10 ± 2.25 |
| **Carbohydrates (g/100g)** | 2.74 ±0.78 |
| **Calorific value (Kcal/100g)** | 71.24 ± 0.84 |

*(Continued on next page)*

**Results and discussion**

After comparison with the literature, it was possible to conclude that artisanal canning presented high levels of moisture (82.46±2.02 g/100g), low levels of ash (0.23±0.26 g/100g), lipids (2.32±0.15) and calories (71.24±0.84 Kcal/100g), and moderate levels of protein (12.10±2.25 g/100g) and carbohydrates (2.74±0.78 g/100g).

After comparison with the literature, it was possible to conclude that artisanal canning presented high levels of moisture (82.46±2.02 g/100g), low levels of ash (0.23±0.26 g/100g), lipids (2.32±0.15) and calories (71.24±0.84 Kcal/100g), and moderate levels of protein (12.10±2.25 g/100g) and carbohydrates (2.74±0.78 g/100g).

The importance of these data for the Amazon is significant, as they highlight the potential of artisanal fish canning as a nutritious and economically viable source of food in the region. The high moisture content contributes to the palatability of the product, while the low ash and lipid contents are indicative of a healthy food with low levels of impurities and fat. Moderate amounts of proteins and carbohydrates ensure nutritional balance, which is essential for the diet of local populations.

According to Gonçalves (2021), the importance of developing and producing fish-based products is not limited to: food safety; maintaining quality; including species that are rarely consumed; adding value to unattractive fish; and, most importantly, encouraging fish consumption. Therefore, fish-based products are among the most important food products traded internationally.

**Conclusion**

These results demonstrate the viability of producing canned fish in the Amazon, using local ingredients and artisanal methods, promoting sustainability and the valorization of regional natural resources. Thus, the dissemination of these data at scientific events is crucial to increase the visibility and recognition of the nutritional and economic value of these products. Thus, the canned fish prepared by this study is easy to prepare and handle, and can be replicated at low cost, since materials and ingredients that can be easily found in markets and fairs are used. The canned fish has been shown to have a good dietary standard, as it has nutritional components that can be used in diets that require proteins and lipids, which nutritionally justifies encouraging the consumption of these artisanal canned fish.

# PHOSPHORUS REQUIREMENTS IN SEA-CAGE FARMED ATLANTIC SALMON WITH AN EMPHASIS ON BONE HEALTH AND DIGESTIBILITY

Lucia Drábiková*, Saskia Kröckel, P. Eckhard Witten, Guido Riesen, Paul Morris, Thomas W.K. Fraser, Per Gunnar Fjelldal

Reproduction and Developmental Biology, Institute of Marine Research, Matre, Norway
Evolutionary Developmental Biology, Ghent University, Ghent, Belgium

**The role of phosphorus in salmon aquaculture**

Phosphorus is an essential nutrient for Atlantic salmon (*Salmo salar*, L.) due to its role in cellular metabolism and bone mineralisation. As the level of phosphorus in water is low and its form in readily available ingredients is often poorly digested, commercial fish feeds are supplemented with highly digestible inorganic phosphorus, a limited and expensive resource. It is therefore essential that salmon are fed only the necessary amounts to not only reduce costs, but to prevent the release of excess phosphorus into the environment. The required dietary phosphorus levels during the grow-out phase of farmed salmon, which is when feeding intensity is highest, remain to be specified. The range of total phosphorus in commercial diets can be relatively high (9.4–3.0 g/kg total P) (Chatvijitkul et al., 2017) compared to the recommendations (8.0–10.0 g/kg total P) (National Research Council, 2011). The Norwegian annual production of Atlantic salmon was 1.5 Mt in 2021 while the average phosphorus emissions from salmon farming reached 16.3 kt (Pandit et al., 2023). With the salmon industry expected to reach 5 Mt annually by 2050, it is essential to ensure proper phosphorus management.

**Experimental design**

In the current study, sea-cage reared salmon were located at the MOWI Feed Research Station (63°N, 7°E) from December 2022 (1.8 kg), through April (2.8 kg), until July 2023 (4.2 kg). The temperature was 5–9 °C (December-April) and 7–14 °C (April–July). Salmon were fed one of six diets (A–F) formulated to contain a total phosphorus level of either below (Diets A–D, 6.1, 8.0, 8.7, and 9.5 g/kg, respectively), at (Diet E, 10.4 g/kg), or above (Diet F, 11.2 g/kg) the current recommendations. The study involved 24 sea-cages, with 4 replicates per diet and 90 fish per sea-cage. Diets with 57.4% plant protein and 7.5% fish meal were supplemented with mono-ammonium phosphate (MAP) (Diets B–F). The MAP inclusion rate in Diet A was negligible and raw materials were the main source of dietary phosphorus. Response parameters were growth, phosphorus digestibility, phosphorus excretion and several skeletal health indicators, namely bone mineralisation and bone deformities since inadequate or excess dietary phosphorus content can play a role in deformity development. In addition, bone mechanical strength measured as resistance of the vertebra to deformation under stress, was analysed as it is a sensitive biomarker for detecting sub-optimal phosphorus levels.

**Growth and bone health**

In all diet groups, growth was slower from December–April compared to later in April–July. From December–April, all diet groups grew at comparable rates of about 0.62 mm/day and 0.35% body mass/day. The general growth rate in animals fed Diets B–F increased between April–July to 0.98 mm/day and 0.55% body mass/day. However, during this latter period, Diet A was not able to sustain the same growth rate with the fish growing significantly slower at 0.77 mm/day and 0.47% body mass/day. According to radiological examination there were no dietary differences in the prevalence of deformities except for the occurrence of increased radiolucent spaces due to large areas of non-mineralised bone in those fish fed Diet A. In April, animals fed Diet A already showed a significant reduction in vertebral ash content and mechanical strength by 20% and 39%, respectively, compared to those fed Diets B–F. In July, vertebrae of animals fed Diet B also exhibited a 7% and 18% reduction in ash and mechanical strength, respectively, compared to animals fed Diets C–F.

**Phosphorus digestibility and excretion**

Phosphorus digestibility was lower in December-April compared to April–July where there was a most notable increase in animals fed Diets B–D. The increased phosphorus digestibility led to an increase in the level of available dietary phosphorus from 2.3, 3.7, 4.1, 4.6, 5.6, and 5.8 g/kg in Diets A–F, respectively, in the period December–April, to 2.5, 4.2, 4.6, 5.1, 5.8, and 6.1 g/kg in April–July.

*(Continued on next page)*

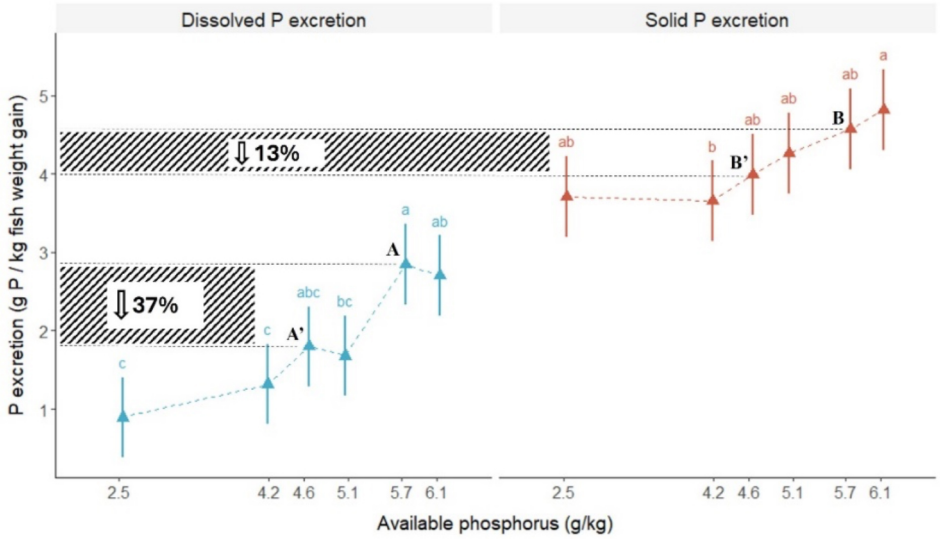

Figure 1. The calculated estimated rate of phosphorus (P) excretion in animals fed different levels of available P. The cross-out areas specify the potential reduction in dissolved and solid P excretion between the currently used P levels in commercial diets (A, B) and the updated requirements based on this study (A', B'). The statistical significance between diet groups is specified with different lowercase letters.

## Conclusions

The levels of available phosphorus required for regular bone mineralisation and mechanical strength were 3.7 g/kg (Diet B) in the period December–April and 4.6 g/kg (Diet C) in April–July. Therefore, there is potential to reduce the total dietary phosphorus content in current commercial feeds, here represented by Diet E (10.4 g/kg), by 16–24%. This will not only reduce feed costs, but may also significantly lower the total phosphorus loss into the environment by estimated 13% reduction in solid phosphorus excretion and 37% reduction in dissolved phosphorus excretion (Fig. 1).

# ADVANCES IN THE PROOF OF CONCEPT OF A FEED RESTRICTION STRATEGY FOR IMPROVED SUSTAINABLE PRODUCTIVITY IN ARCTIC CHARR (*Salvelinus alpinus*) CULTIVATION: BANKING ON LIPID METABOLISM DYNAMICS TO GENERATE FULL CATCH-UP GROWTH

C. Drouin-Johnson*, N.R. Le François, G.W. Vandenberg, F. Dupuis and S.G. Lamarre.

Consultants AquaNova, 4733 La Fontaine st, Montreal, QC, Canada H1V 1R1
Physiology and Aquaculture Conservation Laboratory, Biodome of Montreal/Space for Life, 4777 Pierre De-Coubertin ave, Montreal, QC, Canada H1V 1B3
Email: cdjohnson@aquanova.biz

The charr (*Salvelinus sp*.) genus is native to the Holarctic realm and displays adaptative metabolic mechanisms that rely on lipids to sustain energy homeostasis through prolonged overwinter feed scarcity and short nutrient rich spring-summer cycles. Arctic charr (S. alpinus), the most starvation-adapted species exhibits outstanding coping mechanisms that stem from dynamics in lipid class composition, storage-to-mobilization ratio, and endocrine regulation when fat storage tissues are depleted. This metabolic cascade can result in body mass loss that can be compensated for via the triggering of an accelerated growth response associated with improved feed conversion rates upon refeeding. Accordingly, feed restriction (FR) as a production strategy in Arctic charr aquaculture is increasingly studied to reduce costly feeding operations and phosphorous discharge provided, 1) fish can withstand substantial FR without jeopardizing growth, or 2) complete compensatory growth (CG) is successfully expressed following severe FR. In the past decade, our team has tested various FR models applied at commercial-scale within production cycles of partner local fish farmers and was able to adapt the approach based on environmental parameters, farm site, species and growing-out to distribution timeframes. We recently integrated notions of physiological phases of starvation (Phase I: Glycogenolysis; Phase II: lipolysis to fatty acid oxidation; Phase III: Protein catabolism) for the development of adapted FR protocols essentially based on the predispositions of Arctic charr to delay the transition to protein catabolism (Phase III), thus extending feed restriction-associated productivity benefits. Recent experimental results indicate a whole carcass lipid depletion threshold target of 18% in sub-adults (180g) prior to refeeding is associated with the fastest compensatory growth response ever reported in the literature. Standard lipid content determination techniques provided *a posteriori* values, required lethal techniques and costly analytical protocols. In a most recent trial conducted on adult fish (>400g), we tested a non-invasive approach to gauge lipid depletion *in continuo* during a FR sequence using microstrip sensor technology. The strategy successfully identified a >18% depletion that signaled the perfect refeeding timing in early spring that triggered a complete CG response, unveiling scalable sustainable profitability.

# TOWARDS CIRCULAR BIOECONOMY: NUTRITIONAL AND BIOCHEMICAL CHARACTERIZATION OF SEA LETTUCE (*Ulva* SP.) CULTIVATED IN ASSOCIATION WITH A FISH FARM

Aires M. Duarte[1,2*], Joana Assunção[4], Isabel Sousa Pinto[1,2], Isabel Costa[1,3]

Email: airesmduarte@gmail.com

Fish aquaculture produces a nutrient-rich water that may impact the surrounding ecosystems if discharged. Integrating aquaculture with macroalgae cultivation could provide a sustainable solution by simultaneously cleaning this water, producing valuable biomass and boosting circular bioeconomy. *Ulva* sp., a fast-growing green seaweed, has high potential for bioremediation, as it efficiently absorbs excess nutrients from aquaculture waters (Bolton et al. (2016), Shpigel et. (2019), Duarte et al. (2025)). Additionally, *Ulva* species have a rich and diverse composition, containing significant levels of proteins, fibers, sulfated polysaccharides such as ulvan, pigments, vitamins, and minerals (Bolton et al. (2016), Hofmann et al. (2024)). However, the values of these nutritional and biochemical compounds can vary according to the season and the culture conditions, including stocking density and flow rate (Hofmann et al. (2024)).

The objective of our study was to perform a characterization of the nutritional and biochemical properties of *Ulva* sp., which was cultivated under three stocking density levels (D1, D2 and D3) and two flow rate levels (low–F1 and high–F2) in the water from a fish farm for one year. Every month, the nutritional and biochemical composition was assessed in term of protein, total polysaccharide, ash, carbon, nitrogen, pigment (chlorophyll *a*, *b* and total carotenoid), total phenolic content and antioxidant capacity. A $Z_{score}$ was performed for each variable across cultivation conditions and seasons to assess the best performance.

Results showed that *Ulva* sp. composition varied over the year and across the stocking density and flow rate. Protein (17.2-30.2%), polysaccharide (9.6-41.4 %), ash (12.9-25.8 %), carbon (25.1-36.5%) and nitrogen (3.4-6.0%) content, total pigments (3.6-11.1 mg g $DW^{-1}$), phenols (0.6-2.6 mg /g DW) and antioxidant capacity (14-86 mg TE/ g DW).

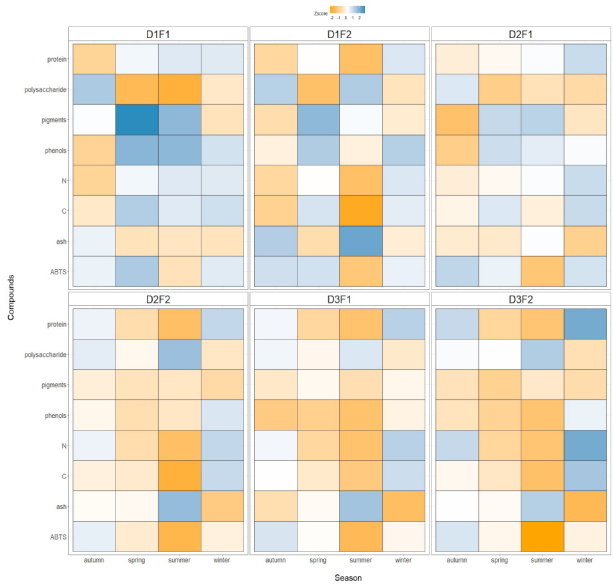

Figure 1. Heatmap of the *Ulva* sp. composition contents (Z-scored) over the season and the cultivation conditions.

*(Continued on next page)*

Cultivating *Ulva* sp. at D1F1 showed an overall high performance (blue color dominance, Fig.1), in terms of pigment, phenol, nitrogen, carbon and protein content, especially in spring/summer. Additionally, this cultivation condition showed high productivity in terms of growth (data not shown). This work will explore the influence of the cultivation conditions and the seasonal effect on this nutritional and biochemical composition of *Ulva* sp.

## Introduction

The EU is the world's largest importer of seafood (3,500 M€) with a self-sufficiency rate of only 27.8% in 2023 while EU seafood demand is increasing. The EU with its strategic guidelines for a more sustainable and competitive aquaculture sector, as well as strategies for the development of the blue bioeconomy, has clear ambitions to increase production from sustainable aquaculture. An integral part of this strategy is the enhancement of low trophic species production and the introduction of novel farming methods able to sustainably intensify aquaculture production, such as the development of Integrated Multi-Trophic Aquaculture (IMTA) systems. However, the uptake of IMTA and low trophic species culture by the industry has been disappointing due to significant challenges linked to systems complexity and the dominance of economic considerations in the decision-making process. However, low trophic species production can be integrated with higher trophic fed aquaculture species in a way that the wastes from the higher trophic species become resources for lower trophic levels using IMTA systems. Importantly, the strong but narrow and static economic focus on private costs and benefits that has so far limited IMTA uptake neglects environmental externalities and associated societal costs and benefits, such as utilisation of wastes at present causing eutrophication and stimulation of production circularity and pathways towards zero-carbon emissions. The present state of the art acknowledges these possible environmental benefits of low trophic aquaculture and IMTA, but it does not quantify nor value those benefits, nor the societal gains from increased resilience. The challenge is to generate this data and show stakeholders the environmental and economic benefits of low trophic species culture and IMTA.

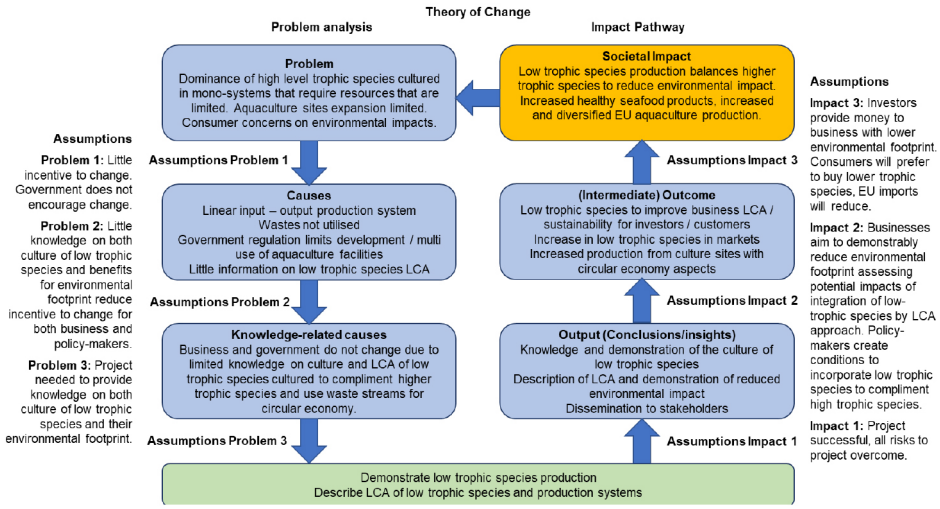
BLUEBOOST aims to address these challenges:

a) Increase the aquaculture industry´s uptake of technologies for the culture of low trophic species together with established fed species to diversify and increase aquaculture production.
b) Describe and quantify the environmental and economic benefits of the culture of a wide range of low trophic species together with established fed species for stakeholders, in the aquaculture industry, policymakers and consumers.

## Materials and Methods

BLUEBOOST partners have set up six IMTA case studies integrating the culture of low-trophic species (omnivorous fish, crayfish, molluscs, sea cucumber, sea urchin, seaweed, oysters and plants) with established aquaculture species (fish and shrimp) in Spain, Portugal, Italy, Poland and Brazil. In order to objectively evaluate, quantify, compare and adaptively reduce the environmental impacts of aquaculture with the implementation of IMTA production systems, Life Cycle Assessment (LCA) is used to assess the environmental impact (e.g. use of energy, land, water and greenhouse gas or nutrient emissions) of products and supply chains, a method underlying the EU Product Environmental Footprint (PEF) standard. The economic viability of these novel systems will also be assessed as profitability is a prerequisite for wider uptake and has been an obstacle for the development of IMTA systems to date. BLUEBOOST is an impact driven project that has applied the methodology of the Theory of Change to define pathways that show how project outputs can be transformed through communication to outcomes and societal change.

*(Continued on next page)*



## Results and Discussion

At the heart of the required changes is the industries' ambition to sustainably intensify production activities and maximise economic return, together with society's legitimate expectations to see the environmental footprint of goods and services being reduced. BLUEBOOST proposes to accelerate change in the aquaculture industry by addressing significant knowledge gaps that exist in the conceptual development, practical implementation and regulation of integrated aquaculture systems (Problem analysis) to provide outcomes and a clear pathway to change. BLUEBOOST outcomes predict the aquaculture industry will improve environmental credentials of businesses and products, consumers will demand low-carbon impact products and business investments and policymakers will provide a positive environment for the co-culture of low trophic and established species and deploy regulation to capture waste and reduce pollution. Therefore, Government policy and changing expectations of investors and consumers will drive aquaculture transition to carbon neutrality as shown in the impact pathway in the Theory of Change figure. This win-win scenario will deliver improved diversification of blue food / feed products and, at the same time, will increase production volumes to improve business economic returns combined with a reduced environmental footprint. Therefore, BLUEBOOST can deliver a concrete roadmap for the aquaculture industry to demonstrably reduce its environmental impact and increase sustainable blue food and feed production that can lead to societal transformation.

This societal transformation would generate changes such as: large increase in production of low tropic species, sustainable carbon neutral aquaculture, less pollution, less eutrophication, more wealth in rural coastal areas, improved costal environment, restored ecosystems, more species diversity and healthier diets.

## Introduction

The flathead grey mullet (*Mugil cephalus*) has been recognised as an economically important euryhaline and eurythermal species with potential for aquaculture diversification in the Mediterranean and other regions, such as the Republic of Korea, Taiwan, and South Africa. The species positive attributes for aquaculture include good adaptation to captivity, rapid growth (Whitfield et al., 2012), omnivorous and detritivore feeding habits (Vinatea et al., 2018), and a valued food market including "bottarga" (the roe of fully mature females) with a market value exceeding 200 euros per kilogram. However, a bottleneck for mullet aquaculture development is reproductive control in captivity. Depending on the region and the broodstock holding system, reproductive dysfunctions have been reported to arrest reproductive development. In intensive systems mullet exhibited a severe reproductive dysfunction where the females fail to progress through the vitellogenesis phase and males fail to generate fluid sperm. Studies in IRTA have overcome these severe reproductive dysfunctions with a protocol of weekly injections of recombinant gonadotropins (rGth) (recombinant follicle stimulating hormone – rFsh and luteinizing hormone - rLh) to induce gametogenesis and spawning (Ramos-Júdez et al., 2022). The aim of this study was to use the rGth protocol to induce spawning outside the natural spawning period and further characterise the quality of gametes for larval culture of mullet.

## Material and Methods

The experiment was conducted between March 20th and July 31st, 2023, to induce gametogenesis in mullet using recombinant hormones. The experiment involved 15 mullet randomly selected from a stock of 38 wild adult mullet introduced into IRTA´s facilities (IRTA Aquaculture, Centre de La Rápita, Spain) between 2015 and 2018. Eight females and seven males were divided into an rGths (supplied by www.raraavis-bio.com) group that was treated species specific recombinant follicle stimulating hormone and recombinant luteinizing hormone and a control group treated with saline. The eight females selected for the study had 105.8 ± 5.81 $\mu$m oocyte diameter. The treatments of the females initiated on staggered dates, every two weeks a pair of one rGths female and one control female received the first recombinant hormone and saline respectively. The treatment of each pair commenced on March 20, April 3, April 17, and May 2, 2023. This programmed the spawning of the females to be every two weeks to facilitate live food production for the larval rearing. The rGths (rFsh and rLh) were administered to mullet following the protocol described by Ramos-Júdez et al. (2022). The eggs were incubated under constant conditions, and hatched larvae were transferred to different 100 and 500 L tanks. The larvae were reared with green water (microalgae Tetraselmis Chuii and Isochrysis galbana), rotifers, Artemia and Gemma wean diets (Skretting) based on protocols from Vallainc et al., (2021). Larval growth, development and survival were registered.

## Results & discussion

In the present study, both female and male mullet were induced with rGths to mature and spawn in June – July, a period outside the natural spawning season of wild populations, which typically occurs in September — October in the Western Mediterranean. All four females were during a 13-week period induced from the early stages of pre-vitellogenesis to complete maturation and ovulation. Over a 5-week period, all three rGth treated males developed from having no sperm present to producing and releasing sperm with spermiation sustained for 10 weeks. Three females spawned with males to give fertilised eggs that were incubated and larvae cultured. Juveniles were obtained with a maximum survival of 14.1 ± 5.2% to 42 days post hatch (final experiment day). In contrast, control females and males remained in the early stages of gametogenesis and did not produce viable gametes, highlighting the success of out-of-season induction with rGths. The present study has for the first

*(Continued on next page)*

time demonstrated that rGth hormones can be employed to induce gametogenesis, maturation and spawning of a teleost species out-of-season. Egg and larval quality were sufficient to show that, with further refinement, these protocols can be used by the aquaculture industry as a basis for juvenile production. The high efficacy of induced maturation, over 90% observed in the present and previous studies that developed the protocol, indicate that it offers an attractive alternative for breeder management. Therefore, the findings of this study hold crucial implications for aquaculture, as the culture of this species relies heavily on wild juvenile resources, with hatchery-produced juveniles being scarce.

# IMPROVING PELLET WATER STABILITY IN AQUAFEED PRODUCTION WITH INTACT AQUA

Julia Dvorska*, Maren Ranheim, David Hines, Patrick Badger, Mathieu Calmont and Tom Stylo

Borregaard
P.O B Hjalmar Wessels vei 61721 Sarpsborg Norway
julia.dvorska@borregaard.com

## Introduction

In aquafeed production, pellet water stability is a crucial quality parameter—especially for species such as shrimp, which consume feed slowly from the pond bottom. Poor pellet stability can result in nutrient leaching, increased feed waste, and deterioration of water quality. Using effective pellet binders can significantly improve feed performance, animal health, and production efficiency.

This study compares a newly developed non-synthetic binder, Intact Aqua, with a conventional urea-formaldehyde-based binder (PMC), banned in many regions of the world, focusing on improvements in/maintaining water stability, the energy use/ processing improvements are secondary benefit.

## Materials and methods

The trial was conducted at a commercial shrimp feed facility in Central America. A standard shrimp mini pellet formulation was used across all treatments. The control diet included 0.22% of a conventional urea-formaldehyde-based binder (PMC), while test diets contained Intact Aqua at 0.30%, 0.50%, and 0.75% inclusion levels. Each treatment was produced in a 5.5 metric ton batch.

## Results

The most notable improvement was observed in pellet water stability: +4% improvement at 0.3% inclusion, +6% improvement at 0.5% inclusion; +16% improvement at 0.75% inclusion (Fig. 1). Even at a similar dosage as the reference we found improvement of the water stability. These results demonstrate that Intact Aqua provides strong binding effect similar or better than PMC, helping pellets remain intact longer in water. This is essential in shrimp farming, where feed often remains in water for extended periods.

Intact Aqua also improved several production parameters: conditioning temperature increased by +0.8°C to +5.9°C, supporting better pellet formation and durability (Fig. 2) Pellet mill amperage decreased by up to 6.2%, reducing energy consumption (Table 1). Production throughout was also increased, pellet mill performance was consistent and stable.

This trial shows that Intact Aqua is an effective and sustainable pellet binder for aquaculture. It clearly improves pellet water stability, which is critical for shrimp and other aquatic species, while also enhancing processing efficiency and reducing energy use. These combined benefits make it a sustainable, high-performing alternative to synthetic binders in the aquafeed industry.

# EUGENOL-DERIVED SELF-ASSEMBLED NANOPARTICLES (E-SAN) AS A FUNCTIONAL FEED IN WHITE SHRIMP *Litopenaeus vannamei*

Sefti Heza Dwinanti*, Po-Tsang Lee, Chih-Ching Huang, and Anisha Anand

Department of Aquaculture
National Taiwan Ocean University
Keelung, Taiwan
20224
sefti.heza@unsri.ac.id

Eugenol-derived self-assembled nanoparticles (E-SAN) offer potential benefits to shrimp immunity due to their antioxidant and antimicrobial properties. This study evaluates the effects of E-SAN on growth performance and shrimp immunity, particularly its protection against Vibrio parahaemolyticus infection (AHPND). The experiment was divided into two groups: one group was subjected to challenge tests, while the other was used to observe growth performance. Twenty shrimp, with an average body weight of 4.6 ± 0.3 g per shrimp, were reared in aquariums (60 × 45 × 40 $cm^3$) containing 96 L of filtered seawater in a circulatory system maintained at a temperature of 28°C. The shrimp were fed commercial pellets supplemented with three different concentrations of E-SAN: 0 µg $g^{-1}$, 200 µg $g^{-1}$, and 400 µg $g^{-1}$. The results revealed that functional feeds containing E-SAN protected the shrimp from AHPND without negatively affecting their growth performance. The protective effects of E-SAN were observed as early as the first week of administration and persisted until the end of the culture period. However, further analysis is needed to optimize the dosage, as histological examination of the hepatopancreas showed structural changes. These findings suggest that E-SAN has great potential as a dietary supplement to enhance shrimp health and resilience against infectious diseases.

# SURVIVAL OF EMBRYOS AND FRY OF SEA TROUT (*Salmo trutta M. Trutta*) GROWING FROM EGGS EXPOSED TO DIFFERENT CONCENTRATIONS OF SELENIUM DURING EGG SWELLING

K. Dziewulska, L. Kirczuk, R. Czerniawski and M. Kowalska-Góralska

Department of Hydrobiology
Institute of Biology
University of Szczecin
Felczaka 3c
71-412 Szczecin, Poland
Email**:** katarzyna.dziewulska@usz.edu.pl

**Introduction**
Selenium-poor areas are defined in the Earth. Adequate selenium (Se) consumption enhances the health and growth of organisms, but overdose of it can be harmful and pathogenic. The study's objective was to analyse the impact of short-term exposure of sea trout fertilised eggs to inorganic selenium ($SeO_2$) at concentrations from 0 to 32 mg Se $L^{-1}$ to find the optimal and toxic dose of Se on early fish development. Se accumulated in the body, embryos' survival rate, and growth in the first four months of life was examined.

**Materials and methods**
Eggs used in the study were from wild sea trout (*Salmo trutta* m. *trutta* L.) entering the Rega River for spawning (NW Poland). Se content in unfertilised egg and hatchery water was very low (selenium-poor area). In egg, the element concentration was 1.6 μg Se $g^{-1}$ (d.w.) (assuming 65% moisture of eggs) and in aquarium water of 0.04 μg Se $L^{-1}$.

Eight concentrations of selenium 0, 0.5, 1, 2, 4, 8, 16 and 32 mg Se $L^{-1}$ ($SeO_2$) dissolved in aquarium water. Fifty fertilised eggs were placed in 100 mL of selenium solution for 3 hours to swell at 6 °C. After the swelling, the eggs were rinsed with separated aquarium water and transferred to baskets floating in the basins (three repetitions) with a closed water circuit. The survival rate was monitored by counting up to the age of four months after hatching.

**Result**
Accumulation of Se in the body of hatch increased with the increase of element concentration in the aqueous environment during egg swelling. Swelling of fertilised eggs in water supplemented with Se at a concentration from 0.5 to 8 mg Se $L^{-1}$ was associated with a slightly positive impact on the hatching rate. Higher concentrations of Se were harmful to embryo survival, while 32 mg Se $L^{-1}$ was lethal. The selenium content in hatch body in the control group average 3.6 ± 0.2 μg $g^{-1}$ (d.w.), whereas, in the 16 Se group, selenium concentration was 5.4 ± 0.3 μg $g^{-1}$. The survival of fry was similar in all groups, while the fry length and weight correlated positively with Se concentration in its body. In four-month-old fry the mean concentration of selenium in the fish body in the 16 Se group was 4.9 μg $g^{-1}$.

**Conclusion**
In Se-poor areas, immersion of fertilised eggs in water enriched with Se during egg swelling can be used to supplement the deficient element to fish. This innovative method can be implemented in aquaculture to improve breeding outcomes. Se concentration added to water should be adjusted to the selenium compound, fish species, and Se's content in the yolk.

In the sea trout studied, we recommend immersing fertilized eggs during swelling in Se concentrations of 4-8 mg $L^{-1}$ as $SeO_2$ for practical use in hatcheries.

**Funding:** Co-financed by the Minister of Science under the «Regional Excellence Initiative» Program for 2024-2027 (RID/SP/0045/2024/01)

# OPTIMIZING OFFSHORE AQUACULTURE: USING REAL-TIME WAVE AND CURRENT DATA TO OPTIMIZE OPERATIONS AND MINIMIZE EXPENDITURES

J.Eggleton*

Jasmine.eggleton@sofarocean.com

As aquaculture farms migrate further offshore, real-time environmental monitoring has become increasingly critical. This data informs farm design, feeding schedules, and ongoing operations in harsher conditions. Traditional monitoring systems are expensive, challenging to deploy and recover, and lack real-time capabilities for rapid decision-making.

The Spotter platform is a modular, rapidly deployable marine sensing buoy that delivers real-time surface and subsurface data to power better decisions. Users can attach up to two single-point acoustic Doppler current sensors at depths from 5 to 50 meters, ideal for net and mooring designs at aquaculture sites. The Spotter also supports temperature, pressure, dissolved oxygen, and hydrophone sensors, with a CTD and pH probe available by late 2025.

The Spotter Platform collects the wave and current data and transmits them in real time via satellite or cellular networks making them accessible through the Spotter Dashboard and API. The API seamlessly integrates with existing aquaculture specific software such as Aquacom, allowing entire organizations to leverage real-time data. Deploying multiple Spotter buoys allows for the co-location of current and wave measurements, enabling operators to make optimized decisions regarding site selection, allowing for a reduction in equipment failure risks, and improving feeding efficiency. Real-time access enables adaptive management, reducing downtime and increasing resilience to extreme weather. This equipment gives farm owners the ability to gain their NS9415 stamp.

The Spotter Platform provides a cost effective co-located monitoring solution that lowers capital expenditure for offshore aquaculture operations through real-time observations. Operating costs decrease with the reduction in cost for sensor deployment and installation, and improved decision-making for more streamlined maintenance, enhances productivity. Case studies will demonstrate cost benefits and operational improvements, reinforcing the value of real-time ocean data for optimizing offshore aquaculture.

# RACING TO THE FINISH: HOW EARLY-LIFE WARM REARING UNDERMINES CARDIORESPIRATORY PERFORMANCE AND HEAT TOLERANCE IN RAINBOW TROUT

Andreas Ekström[1]*, Heidi Mortensen[1,2], Laila Jan[1], Lucas Zena[3], Ida Beitnes Johansen[4], Michael Frisk[5], Albin Gräns[6], and Erik Sandblom[1]

Email: andreas.ekstrom@bioenv.gu.se

**Background**
In salmonid aquaculture, early-life rearing conditions can have long-term effects on fish performance and welfare. Elevated-temperature rearing regimes that promote rapid growth have been linked to increased post-stress mortality, possibly due to misshaped heart morphology observed in both fast-growing Atlantic salmon (*Salmo salar*) and rainbow trout (*Oncorhynchus mykiss*) (Brijs et al., 2021; Frisk et al., 2020; Vindas et al., 2024). Additionally, farmed salmonids often exhibit coronary arteriosclerosis causing blockage of coronary artery flow and compromised myocardial oxygen and nutrient supply, a condition that is likely exacerbated by stressful rearing conditions (Brijs et al., 2021). The implications of these cardiovascular pathologies on cardiac and metabolic performance and stress resilience remain unclear. To address this, we investigated cardiorespiratory physiological and cardiac morphological consequences of warm rearing conditions in rainbow trout, raised under two temperature regimes at a commercial fish farm.

**Material and methods**
Warm- and cold-reared trout (n=32 per group) were raised under temperature regimes differing by 4–10°C for 7–8 months and then acclimated to a common temperature of 10°C for 4–7 weeks. Fish were surgically instrumented with electrodes to monitor heart rate via their electrocardiogram (ECG) and assess cardiac performance. After overnight recovery, heart rate and metabolic rate (via intermittent respirometry) were measured at rest and after an exhaustive chase protocol to attain maximum values. Aerobic scope and heart rate scope (maximum-resting values), reflecting the capacity to increase these performances above resting levels when needed (e.g., during stressful events), were calculated. The following day, fish were subjected to an acute warming protocol to determine critical thermal maximum ($CT_{max}$), after which they were euthanized for assessments of heart morphology. We evaluated the shape of the ventricle and the alignment of the *bulbus arteriosus*, and ongoing analyses will provide information about the prevalence and severity of coronary arteriosclerosis.

**Results**
Preliminary data show that warm-reared trout had significantly higher growth rates, more rounded ventricles (lower height:width ratio), and a misaligned *bulbus arteriosus* compared to cold-reared trout (Fig. 1A–C). Warm-reared fish also showed parallel elevations of resting and maximum heart rate (Fig. 1D). This led to a reduced heart rate scope. Furthermore, warm-reared trout had lower aerobic scope due to reduced maximum metabolic rate (Fig. 1E). Heat tolerance was also impaired in warm reared trout, as evidenced by a lower $CT_{max}$ (26.3°C vs. 27.3°C).

**Conclusions**
Our findings show that warm rearing accelerates early growth but induces cardiac remodeling linked to impaired heart function, reduced aerobic metabolic capacity, and lowered thermal tolerance in rainbow trout. These physiological impairments may contribute to elevated mortality in aquaculture, particularly during stress from *e.g.,* handling, treatment, and transport. Rearing protocols that prioritize growth should be re-evaluated, as they may compromise fish welfare and overall stress resilience. Ongoing experiments aim to further elucidate the long-term impacts of early-life thermal environments on adult trout health and performance.

## Introduction

The use of fermented feeds for tilapia reared in a biofloc system (BFT) could have positive impact fish physiology and water microbiota. We hypothesize that plant-based fermented feeds will modulate the BFT microorganisms through interactions between the components of the fermented product and the heterotrophic microorganisms present in the water. The objective of this study is to acess the effect of a plant-based fermented feed on the count of microorganisms in the water and intestine of juvenile Nile tilapia (*Oreochromis niloticus*) reared in a biofloc technology (BFT) system.

## Materials and methods

Plant-based feeds for Nile tilapia, fermented for 6 and 18 hours, were compared with a positive control diet containing fishmeal and a negative control diet without animal protein. The experimental design was completely randomized, with four treatments and six replicates. The diets were isoproteic (33% CP) and isoenergetic (4100 kcal $kg^{-1}$). The plant-based feed was fermented with *Lactobacillus acidophilus* following a methodology adapted from Azarm and Lee (2014). Juvenile Nile tilapia (8.3 ± 0.2 g) were distributed into 24 tanks (70 L), with 17 fish per tank. After 60 days, water samples were collected from each tank for microorganism enumeration. Intestinal samples were also collected from three fish per tank for microorganism count analysis. Differences between results were assessed using analysis of variance (ANOVA) and Tukey's test ($P<0.05$).

## Results

Feed fermented for 18h increased ($P<0.05$) the acid lactic bacteria count in the water compared to fish meal and plant-based diets (Table 1). A reduction ($P<0.05$) in *Vibrio* sp. was observed in the water of the tanks that received the feed fermented for 6h relative to the fish meal diet. At the end of the trial, the concentration of heterotrophic bacteria in the intestines of Nile tilapia fed feed fermented for 6h was higher ($P<0,05$) than in the rest of the dietary groups. Levels of intestinal acid lactic bacteria were lower ($P<0.05$) in the fish that received plant-based feeds. The *Vibrio sp.* count was lower ($P<0.05$) Vibrionaceae family in the fish treated with fermented plant-based feeds.

Table 1. Microorganisms count in experimental tanks water and fish intestine after 60 days.

| | Fish meal | Plant-Based | Fermented 6h | Fermented 18h |

*(Continued on next page)*

**Discussion**

The use of fermented feeds positively affected the count of microorganisms in water in the BFT tanks. The increase in LAB during fermentation may have contributed to the reduction in *Vibrio sp.* The use of probiotics has already been demonstrated to be effective in BFT systems to control pathogenic bacteria in water (He et al., 2023). Regarding the bacteria counts in intestine, an increase in the count of heterotrophic bacteria and acid lactic bacteria was observed in fish fed with fermented feeds. The increase in intestinal acid lactic bacteria agrees with the increase count in water samples, since there is generally a sound correlation between the intestinal microbiota in fish and those of the environment (Turner et al., 2022). A similar modulation effect could have been observed in the reduction in *Vibrio sp*. through the feed and biofloc particles.

**Conclusions**

The use of plant based based fermented feeds increased the abundance of beneficial bacteria counts and reduced the pathogenic bacteria in the water of the BFT system and in the fish intestine.

**Introduction**

Fermentation is a bioconversion or metabolic decomposition, carried out by microorganisms that transform complex substrates into simple compounds. During fermentation, secondary metabolites with prebiotic action are produced and the population of beneficial microorganisms with probiotic function increases, which can help control pathogens. Fermentation of feed can improve nutrient utilization (Yang et al., 2023) and intestinal health of fish (Neves et al., 2024). The objective of this work was to evaluate the effect of feed co-fermentation with *Lactobacillus acidophilus* and *Lacticaseibacillus rhamnosus* on the growth performance and intestinal bacteria count of rainbow trout *Oncorhynchus mykiss* juveniles.

**Materials and methods**

Three times (3, 6 and 9h) of feed fermentation were evaluated in comparison with a control feed without fermentation. The experimental design was completely randomized with four treatments and four replicates. Juvenile rainbow trout (initial average weight of 22.2 ± 0.9 g) were distributed in 16 circular tanks with a useful volume of 500 liters at a density of 15 fish per tank. The tanks were interconnected to a recirculation system. A commercial feed for juvenile rainbow trout with 45% crude protein and 4 mm was fermented through solid-state fermentation (Azarn and Lee, 2014). At the end of the experiment (duration of 60 days) performance was evaluated and two animals per tank were collected for intestinal microorganism counts. Differences between results were assessed using analysis of variance (ANOVA) and Tukey's test ($P<0.05$).

**Results**

Fermentation of feed for 3 and 6 hours improved ($P<0.05$) the feed conversion of fish (Table 1). There was also a reduction in consumption ($P<0.05$), but growth performance was not affected ($P>0.05$). Fermentation of feed for 3 and 9 hours improved ($P<0.05$) lactic acid bacteria count in the intestine of fish (Table 2). Heterotrophic bacteria were not affected ($P>0.05$) by fermentation.

Table 1. Productive performance of rainbow trout fed fermented feed after 56 days.

| | Control | Fermented feed 3h | Fermented feed 6h | Fermented feed 9h |
|---|---|---|---|---|
| Final weight (g) | 60.52±6.07 | 65.07±3.85 | 62.16±3.42 | 58.54±3.92 |
| Daily feed ingestion (g) | 1.02±0.08a | 0.91±0.05b | 0.89±0.03b | 0.87±0.06b |

*(Continued on next page)*

**Discussion**

Fermentation improved feed efficiency of the feeds. The colonization of the digestive tract by probiotic bacteria associated with fermentation metabolites may have optimized the digestive process of fish that ingested fermented feed (Yang et al., 2023; Neves et al., 2024). Increased lactic acid bacteria count in the intestine confirms this result. Fermentation is an innovative and promising method that can contribute to the sustainability of aquaculture feeds.

**Conclusions**

Feed fermentation improved feed efficiency of rainbow trout juveniles. Greater colonization of lactic acid bacteria was also observed, indicating improved intestinal health.

# EFFICIENT EXTRACTION OF POLYSACCHARIDES AND PROTEINS FROM *Saccharina latissima* USING ULTRASOUND-ASSISTED DEEP EUTECTIC SOLVENT METHOD: A SUSTAINABLE APPROACH FOR MARINE BIOMOLECULE ISOLATION

Rifna Elenjikkal Jerome[1,2,*], Nilushni Sivapragasam[1], Gaurav Rajauria[1,2]

School of Food Science and Nutrition[1], School of Microbiology[2], University College Cork, Ireland
Email: relenjikkaljerome@ucc.ie

## Introduction

Seaweeds are evolving as ample and sustainable sources of high-value compounds with prospective applications in food, feed, pharmaceuticals, and cosmetics. Brown seaweed *Saccharina latissima* is a robust source of proteins and polysaccharides. However, most existing extraction methods often comprise elevated energy input, extended extraction times, and use of hazardous solvents, which can degrade sensitive bioactive and other targeted compounds (Zhang et al., 2020). Deep eutectic solvents (DES), specifically those based on choline chloride and lactic acid, pose a green alternative, with exceptional biodegradability and solvating power (Dai et al., 2013). When combined with ultrasound-assisted extraction (UAE), which boosts mass transfer through cavitation, the process becomes vastly efficient for solute diffusion and cellular disruption (Chemat et al., 2017). This study explored the application of UAE-DES for the co-extraction of proteins and polysaccharides from brown seaweed biomass.

## Materials and Methods

Dried, ground *S. latissima* was pretreated with 80% ethanol to eliminate lipids, phenolics, and pigments, improving extraction accessibility. A DES was prepared using choline chloride and lactic acid (1:2 molar ratio), with 30% water added to lower viscosity and improve extraction efficiency. The mixture was heated at 60 °C to form a homogeneous solution. UAE was performed with a probe sonicator under variable process parameters of amplitude (70%, 80%, 90%), sonication time (5, 10, 15 min), and feed-to-solvent (F:S) ratio (3%, 5%, 7%), optimized with Box-Behnken design. Extracts were analysed for total protein content (TPC), protein recovery yield (PRY), total soluble carbohydrate (TSC), and carbohydrate recovery yield (CRY). Techniques such as FTIR, SEM, and HPLC were applied to characterize the extract's structural, thermal, and chemical features. Comparative studies were carried out using acidic water (pH 2), ultrasound alone and non-ultrasound methods to determine the competence of DES and UAE.

## Results and Discussion

### Effect of Ultrasound Amplitude

A clear enhancement in extraction efficiency was observed with increasing amplitude. At 90% amplitude and 5 min sonication, TPC and PRY were significantly higher (729.75 µg/mL and 13.32 mg/g, respectively) compared to 70% amplitude (585.75 µg/mL TPC, 9.97 mg/g PRY). The enhancement is credited to effective cavitation and cell disruption, accelerating solubilization of intracellular compounds (Chemat et al., 2017).

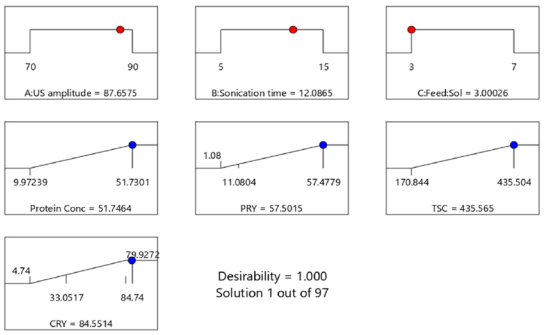

Figure 1: Optimized conditions predicted by Response Surface Methodology (RSM) modeling for the target process parameters.

*(Continued on next page)*

**Influence of Sonication Time**

Prolonged sonication times increased yield, remarkably at increased amplitudes. At 90% amplitude and 15 min treatment, PRY rose to 15.08 mg/g and CRY to 53.33%. However, overexposure without an optimal F:S ratio could lead to compound degradation, highlighting the necessity for a balanced treatment regime.

**Feed-to-Solvent Ratio Effects**

At 3% F:S ratio, yields were increased under optimized amplitude and time, with CRY extending 84.25%. Although a lower solvent volume guarantees more intense solute-solvent interaction, optimal extraction was mostly achieved at 5% ratio, where adequate diffusion and solubilization occurred without dilution effects.

**Optimization and Predicted Responses**

Using response surface methodology (Box-Behnken), the optimal conditions were: 88% amplitude, 12 min sonication, and 3% F:S ratio, yielding predicted responses of TPC: 51.74 mg/g, PRY: 57.50%, TSC: 435.56 mg/g, and CRY: 84.55%. Experimental validation confirmed these trends.

**Comparative Efficiency of Extraction Methods**

Compared to acidic water extraction and ultrasound extraction alone, UAE-DES demonstrated significantly higher yield and purity. Non-ultrasound DES methods, though more efficient than conventional solvents, were subsidiary to UAE-DES, confirming the interactive benefit of cavitation-enhanced solubilization.

**Conclusion**

The research confirms UAE-DES as an advanced, efficient, and green method for the co-extraction of polysaccharides and proteins from brown seaweed. The optimized factors led to significantly greater yields and improved purity of extracts associated with the conventional method. The DES system, being biodegradable and tunable, poses a sustainable extraction platform aligned with green chemistry principles. These protein- and polysaccharide-rich extracts display elevated potential for application in aquatic and terrestrial animal feed formulations, as well as in functional foods and nutraceuticals, supporting the valorisation of marine biomass within circular bioeconomy frameworks.

## Introduction

Freshwater habitats, such as rivers, lakes, and wetlands, host approximately one-third of all vertebrate species while covering less than 1% of the Earth's surface. With such high biodiversity, freshwater ecosystems, compared to terrestrial and marine environments, are more vulnerable and endangered to biodiversity losses, declining ecological function, decreasing natural benefits, and climate change. The relationship between freshwater aquaculture and biodiversity is complex, presenting opportunities and challenges. When managed sustainably, freshwater aquaculture can contribute to reduced pressure on wild fish stocks, habitat restoration (regenerative aquaculture), conservation of endangered species, and support ecosystem services, thus enhancing global and local biodiversity.

During the common carp (*Cyprinus carpio*) production season, earthen ponds accumulate more nutrients than are discharged to the river system. However, seasonal draining of the ponds requires the transfer or harvest of fish (Oct–Dec), which mobilises marked amounts of sediment settled in the bottom of the pond. This often leads to adverse effects on the water quality and biodiversity of the downstream environment. The study aimed to evaluate the impact of common carp farming on the biodiversity of macroinvertebrates and benthic diatoms. The study also aimed to assess the survival of bioindicator species installed downstream of the farm while implementing SAFE filtering technology.

## Materials and Methods

The study was conducted at the ICR carp farm in NW Poland, located on the Piaskowa river, one of the tributaries of the Rega river that opens to the Baltic Sea at Mrzeżyno. The biodiversity assessment involved a comparative evaluation of the species diversity of benthic macroinvertebrates across different seasons (winter, spring, and summer of 2023 and 2024). The overall impact of the common carp farm on diatom communities was assessed above and below the farm. Finally, three bioindicator species (noble crayfish, *Astacus astacus*; thick-shelled mussel, *Unio crassus*; and river water-crowfoot, *Ranunculus fluitans*) were installed below the discharge channel at the time of pond drainage and sediment sequestration with the SAFE filtering system.

Benthic samples were collected using kick sampling from a 1 m$^2$ cross-section area of the river at sampling points. Next, samples were sieved through a 0.5 mm mesh, stored, and delivered to the laboratory, where benthic organisms were separated from the sediment, identified, and preserved in 70% alcohol.

Diatom samples were taken with a toothbrush from the upper surfaces of gobble-sized stones collected from the stream bottom. The sample material from the stones (n = 10) was pooled into one sample. The samples were stored in alcohol and then sent to the laboratory of the Finnish Environment Institute for further processing. In the laboratory, the samples were cleaned of organic material with a strong acid solution. Permanent slides were made to count and identify the diatom individuals.

The primary biodiversity metric employed in the comparative analysis was the Shannon-Wiener diversity index (H'). The method developed in Zar (2010) was applied to assess the significance of differences. The analysis was conducted using the sample-size-based rarefaction and extrapolation (R/E) sampling curve, which presents diversity estimates with confidence intervals as a function of sample size.

*(Continued on next page)*

**Results and Discussion**

The biodiversity level downstream on the farm was significantly higher after implementing the SAFE filtering technology, which significantly reduced the emission of sediments from the ICR carp farm. Comparative analysis using sample-size-based R/E sampling curves showed that after the discharge process ceased in early winter 2024 (SAFE filtering), interpolated species diversity indicated a significant increase ($p = 0.007$) in benthic organisms' diversity downstream of the farm in 2024, when compared to 2023. Extrapolated predictions further strengthen this observation. Similar significant trends were observed for comparisons obtained for spring ($p = 0.041$) and summer ($p < 0.000$) seasons. These results indicate that minimising sediment release by implementing SAFE filtering technology can contribute to better regeneration of the river ecosystem in early spring, thus helping maintain biodiversity in the freshwater environment.

Taxon richness and H' diversity indices for benthic diatoms were lower in the inflow channel above the farm, compared to the discharge channel of the ICR carp farm. Surprisingly, the proportion of abnormal forms was higher in the inflow than in the outflow channel. This indicates that the carp farm does not increase the proportion of abnormal diatom forms during the production season. The 10 most common diatom taxa varied between the inflow and outflow channels. In winter, *A. minutissimum s.l.* was the most common taxon in the inflow channel, closely followed by *P. lanceolatum* (prefers eutrophic, alkaline conditions)*, A. minutissimum*, and *P. frequentissimum* – together they formed 79% of the diatoms present in the inflow channel. In the same period, the five most common taxa in the discharge channel were planktic taxa from the *Stephanodiscus*, *Cyclostephanos* and *Aulacoseira* genera. Overall, the inflow channel was generally more dominated by one or two taxa, contrary to the discharge channel.

Even with SAFE filtering technology, the discharge of post-production waters into the Piaskowa River caused adverse effects. For instance, some experimental cages were damaged or buried in sediments. The tearing and perforation of the cages by objects carried by the river influenced the distortion of the noted bioindicators' survival rate. In particular, noble crayfish might have escaped from damaged cages. However, in one of the undamaged cages, a 100% survival rate of noble crayfish was observed, indicating that such a sensitive organism could survive when SAFE filtering technology was implemented. Thick-shelled mussels have limited mobility on the riverbed, making it unlikely that they could escape from damaged experimental cages. The main cause that reduced the survival rates of these animals was the organic and inorganic material that filled the cages. The mortality of thick-shelled mussels downstream of the discharge channel was significantly higher (33.4%) than the control group of mussels located upstream (0%; $p = 0.037$). The selection of the plant bioindicator, river water-crowfoot, proved to be too sensitive to habitat conditions in the Piaskowa River, resulting in 100% mortality regardless of nutrient discharge. SAFE filtering technology allowed the survival of two bioindicator species that had not been observed before in the Piaskowa River, in the most challenging period of the year, i.e., water discharge during fish harvesting.

These findings highlight the potential of SAFE filtering technology to mitigate the negative impacts of sediment discharge during aquaculture operations, supporting macroinvertebrate and diatom biodiversity. While challenges remain in fully safeguarding sensitive species, the technology represents a promising step toward more biodiversity-friendly freshwater aquaculture practices.

# IMPACT OF DIETARY INCLUSION OF BLACK SOLDIER FLY LARVAE MEAL ON THE GUT MICROBIOME OF ATLANTIC SALMON: INSIGHTS FROM FIRST FEEDING AND SMOLTIFICATION TRIALS

Ahmed Elsheshtawy[1,2]*, Benjamin Gregory James Clokie, Miha Pipan, Mónica Betancor, Simon MacKenzie

[1]Institute of Aquaculture, University of Stirling, Stirling FK9 4LA, United Kingdom
[2]Faculty of Aquatic and Fisheries Sciences, Kafrelsheikh University, Kafr El Sheikh City 33516, Egypt
Email: a.m.ahmed@stir.ac.uk

Black Soldier Fly larvae meal (*Hermetia illucens*; BSFLM) is emerging as a sustainable and functional alternative to fishmeal in aquaculture diets. This study investigated the effects of graded dietary inclusion levels of defatted BSFLM on the gut microbiome of Atlantic salmon (*Salmo salar*) at two critical ontogenetic stages: first feeding and smoltification. Fry were fed diets containing 0%, 8%, 16%, or 24% BSFLM for 21 days during the first feeding stage, while pre-smolts received diets with 0%, 5%, or 15% BSFLM during smoltification. Microbial communities from the gut, feed and water were characterised using 16S rRNA gene amplicon sequencing, incorporating a novel titration-based quantification step to enhance library preparation accuracy.

Results highlighted that BSFLM inclusion during the first feeding significantly modulated gut microbiome composition, with distinct community structures observed across diets (Figure 1; PERMANOVA, $p$ = 0.001). BSFLM diets were associated with increased microbial richness and evenness, suggesting enhanced diversity during early gut colonisation. Taxonomic profiling further revealed diet-specific shifts in the relative abundance of key bacterial taxa.

During smoltification, BSFLM inclusion also altered the gut microbiome, with all insect meal diets exhibiting consistently higher microbial richness compared to the control. Taxonomic analyses revealed diet- and time-dependent shifts in microbial composition, reflecting dynamic restructuring of the gut microbiome throughout smoltification.

These findings demonstrate that BSFLM not only serves as a sustainable alternative to fishmeal but also exerts stage-specific modulatory effects on the gut microbiome of Atlantic salmon, with potential implications for fish health and performance.

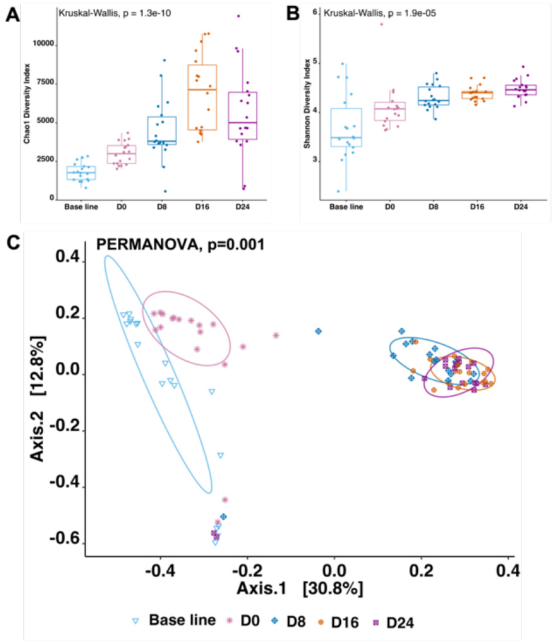

Figure 1. Gut microbiome diversity and composition of Atlantic salmon fry fed diets containing graded levels of BSFLM during the first feeding trial. (A) Alpha diversity metrics showing observed species richness (Chao1 index) and (B) evenness (Shannon index) across different diets (0%, 8%, 16%, and 24% BSFLM inclusion). Significant differences were detected by Kruskal-Wallis tests ($p$ < 0.001). (C) Principal Coordinates Analysis (PCoA) based on Bray-Curtis dissimilarity of gut microbial communities, illustrating distinct clustering by diet (PERMANOVA, $p$ = 0.001), indicating that BSFLM inclusion significantly influenced overall community structure.

# ADVANCING TILAPIA WELFARE IN EGYPTIAN AQUACULTURE THROUGH A ONE WELFARE LENS

Wasseem Emam*

Ethical Seafood Research
20–23 Woodside Place
Glasgow G3 7QL, UK
hello@ethicalseafoodresearch.com

Improving fish welfare in low- and middle-income countries is often framed as a trade-off with productivity. Yet in Egypt, the world's sixth largest producer of farmed *tilapia*, we find evidence that better welfare can go hand-in-hand with improved performance and farmer resilience. This work presents a One Welfare case study of efforts to improve *tilapia* welfare in semi-intensive pond systems in the Nile Delta, where farms are increasingly transitioning to more intensive practices in response to climate and economic pressures.

We describe the rollout of the FAI Tilapia Welfare App—a farmer-friendly digital tool for scoring fish welfare indicators on site—and the lessons learned from its uptake and use across small and medium farms. Drawing on survey, observational and farmer feedback data collected by Ethical Seafood Research and partners from 2022 to 2025, we explore the links between welfare scores, farm conditions, and farmer perceptions, and assess the tool's practical impact on management. The results suggest that improvements in welfare, such as reduced handling stress and more humane fasting and harvest practices, are feasible with minimal investment and can be aligned with existing biosecurity and quality goals.

We argue that centring welfare within a One Welfare framework—considering fish, farmer and environmental wellbeing together—helps build a stronger case for change. This approach is relevant not just to Egypt but to other African aquaculture contexts facing similar intensification trajectories.

# OPTIMISING LARVAL NUTRITION IN FLATFISH USING PROTEIN HYDROLYSATES: GROWTH AND REDOX EFFECTS

## Introduction

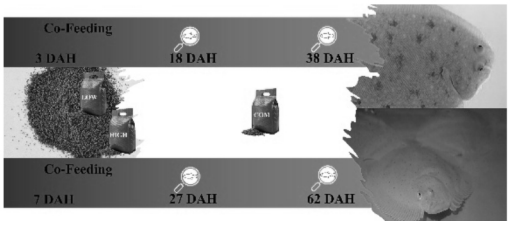
The farming of Senegalese sole (*Solea senegalensis*) and turbot (*Scophthalmus maximus*) is expanding driven by market demand and supported by advances in hatchery technology, including novel microdiets. However, optimising early-stage nutrition remains a major challenge. Live feeds, commonly used at first feeding, are nutritionally suboptimal—particularly regarding protein quality—and have been associated with inconsistent larval growth. Formulated microdiets, used to supplement live feeds in co-feeding regimes or to support earlier weaning, have been proposed as a solution, provided they are adapted to the limited digestive capacity of these altricial larvae. At mouth opening, fish larvae immature digestive tract lacks a functional stomach and gastric glands, limiting their ability to digest complex proteins such as fishmeal. Protein hydrolysates (PH), rich in free amino acids and small peptides, offer a more digestible protein source and have been shown to improve growth and survival in various marine fish species. The inclusion of PH from first feeding may support larvae through metamorphosis and improve long-term robustness, however their peptide profile needs to be optimized, to facilitate digestion, while preventing excessive leaching of amino acids into the water, and also an overload of the absorption and metabolic processes.

## Material and Methods

Two trials were conducted at CCMAR facilities under optimal abiotic conditions using recirculating aquaculture systems. Two dietary treatments were tested in triplicate: LOW (a commercial-like diet rich in a low molecular weight PH) and HIGH (a similar diet rich in high molecular weight PH). Larvae were co-fed from mouth opening - 3 days after hatching (DAH) for Senegalese sole and 7 DAH for turbot - following CCMAR's Aquaculture Research Group protocol. At the end of the pelagic phase (18 DAH for sole and 27 DAH for turbot), larvae were sampled to assess growth, survival, and redox status. Fish were then transferred to benthic rearing systems and fed a commercial-like diet until final sampling at 38 DAH (sole) and 62 DAH (turbot).

## Results

During the pelagic phase, Senegalese sole larvae fed the HIGH diet showed significantly greater growth, suggesting a positive correlation between hydrolysate molecular weight and performance. In contrast, turbot larvae grew better on the LOW diet, indicating an inverse relationship. Redox status was unaffected at the end of the pelagic phase in both species. After metamorphosis, growth remained similar across treatments. However, in turbot, fish previously fed the LOW diet displayed higher total glutathione (GH) and catalase (CAT) activity, along with reduced lipid peroxidation (LPO), suggesting enhanced antioxidant capacity and improved cellular protection.



*(Continued on next page)*

**Conclusions**

The inclusion of protein hydrolysates from mouth opening influenced early growth in a species-specific manner, with opposing effects observed in Senegalese sole and turbot. While redox status was unaffected during the pelagic phase, differences in antioxidant markers post-metamorphosis in turbot suggest that early dietary interventions may shape long-term physiological robustness. These findings highlight the potential of tailored hydrolysate-based diets to optimise early nutrition and resilience in flatfish aquaculture.

## Introduction

Temperature is a critical factor in climate change, with its effects becoming particularly pronounced during heatwaves, defined as periods when the mean or maximum temperature increases by at least 3–5°C for a maximum of three consecutive days. Such conditions significantly impact aquatic environments, often resulting in mass mortalities. The reoccurrence of heatwaves poses a substantial challenge for the salmon and rainbow trout industry. There exists a strong correlation between the heat resistance of fish and their diet. Krill meal (KM) offers a well-balanced amino acid profile akin to fish meal, along with high levels of phospholipids, n-3 polyunsaturated fatty acids (n-3 PUFAs), astaxanthin, vitamins, and minerals. Consequently, KM has the potential to alleviate heat stress in cultured fish due to its functional nutrient content. This study aims to evaluate the phenomic responses rainbow trout fed experimental diets containing 0%, 5%, 7.5%, and 10% krill meal (KM) under a challenging high temperature (14°C-control, 14°C→21°C, and 21°C→23°C). The blood proteome of rainbow trout fed control, KM7.5 and KM10 diets was also assessed to understand the role of the altered proteins in the fish's metabolic and immune systems when maintained at 21°C→23°C.

## Material and Methods

Female rainbow trout juveniles (61.8 g) were placed into two RAS with 16 cylindrical tanks (4 replicates per dietary group) of 350 L capacity at 25 fish/tank. Five isonitrogenous (46% CP) and isolipidic (28% CL) diets were formulated using KM (0, 5, 7.5, and 10 mg/kg; purity: 99%, Aker Qrill Company). Fish were fed twice daily until apparent satiety. During Phase I, four experimental diets were randomly assigned to four replicate tanks using a randomized block design across two RAS. Throughout the 70-day period, fish were manually fed to apparent satiation at 14°C. Following Phase I, one RAS system was designated as the heat stress group. The water temperature of two tanks per experimental group was increased by 1°C daily until reaching 21°C, while the remaining tanks in the second RAS were maintained at 14°C as a control. During Phase II (14°C→21°C), fish continued receiving the same diets, and feed intake was recorded for 7 days. Subsequently, the water temperature in the heat stress group was increased from 21°C to 23°C over 3 days, and the fish were kept at this temperature for 7 more days (Phase III, 21°C→23°C). At the conclusion of each phase, three fish were sampled for fillet fatty acid and proximate composition analysis. Blood samples were only collected for proteomic analysis after Phase III. All data were statistically compared with a two-way ANOVA, where a 4×2 factorial design was followed with diet and heat stress temperature as fixed factors.

## Results

At the conclusion of Phase I (14°C), the final weight (g/fish) and thermal growth co-efficiency (% TGC) in the KM5 group were numerically higher than the control, while there was no significant difference between the KM5 and KM10 fed fish. Overall, no significant differences in feed intake or feed conversion ratios (FCR) were observed across the different diets during Phase I. In Phase II (14°C→21°C), there was a discernible trend showing increased growth in fish fed with KM5 at 21°C compared to those maintained at the control temperature of 14°C. Regardless of the dietary treatment, TGC was significantly higher in fish fed the experimental diets at 21°C than in the fish that had remained at 14°C. In Phase III (21°C→23°C), the final growth of fish fed at 14°C was greater than that of fish fed at 23°C irrespective of the dietary treatments. Fish fed with KM5 and KM7.5 showed higher growth than those fed KM10 during Phase III (21°C→23°C). While fatty acid composition remained unchanged in Phase I, EPA increased in KM5, KM7.5, and KM10 at 21°C. Docosahexaenoic acid (DHA) was sensitive to heat and increased in fish kept at 21°C, irrespective of dietary treatment. A similar trend was observed in fish maintained at 23°C in Phase III. The DHA/EPA ratio was significantly affected by diet and heat stress; however, no significant interaction

*(Continued on next page)*

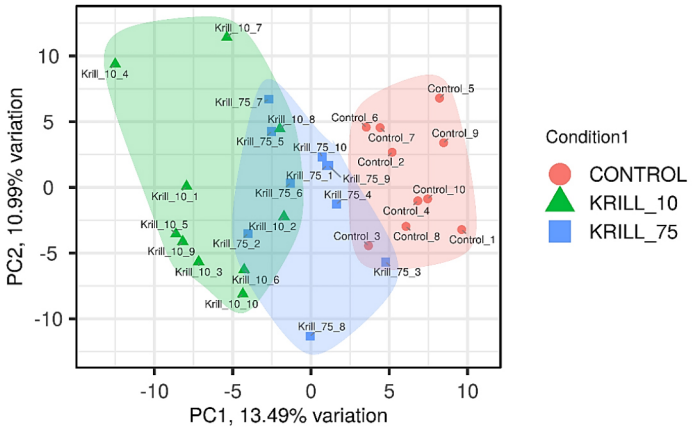

**Fig 1.** Principal Component plot of the blood proteome samples from the three feeding groups of rainbow trout.

effects were observed. Proteomic analysis of rainbow trout exposed to KM7.5 and KM10 revealed significant physiological adaptations (Fig. 1). The higher doses of krill meal (KM7.5 and KM10) elicited stronger upregulation of oxygen transport proteins, particularly haemoglobin subunit alpha-1, and showed comprehensive activation of complement system components, with six proteins significantly upregulated, indicating a better coping ability of trout under challenging temperature, which correlated well with improved survival in KM diets, displaying a dose response, with KM10 resulted in the highest survival at 23°C. Functional analysis of the differentially expressed proteins in the blood proteome will be presented.

**Discussion**

The observations of the present study support the clear benefits of KM in the rainbow trout diets under heat-stress conditions with better growth and survival. The primary phenomic responses to KM supplementation are intake-linked and their benefits when used in diets under heat stress. Based on blood proteomic analysis, these results demonstrated a robust cellular response to both the KM7.5 and the KM10 interventions that was not reflected in the growth performance of the fish. This body of work notably makes a strong case for further exploring the use of KM in aquafeeds as a functional ingredient to improve robustness in rainbow trout under heat stress. It is essential to further investigate this aspect to achieve a more comprehensive understanding of the potential benefits of KM inclusion, particularly concerning the purported enhancement of oxygen-carrying capacity under heat stress in actual culture conditions.

# SEASONAL VARIATION IN THE EXPRESSION OF SPECIFIC HEALTH-RELATED GENES IN EUROPEAN SEA BASS (*Dicentrarchus labrax*)

Orhan Tufan Eroldogan*[1,2], Serdar Kilercioğlu[1], Hatice Asuman Yılmaz[1], Ece Evliyaoğlu[1]

Email: mtufan@cu.edu.tr

## Introduction

Understanding the physiology of fish raised in cages is essential to assess their current condition in response to shifting environmental factors, develop protective measures, and enhance their resilience during these times. By boosting the fish's defense mechanisms and minimizing oxidative stress, these adverse effects can be mitigated. In this regard, seasonal sampling was conducted in the cages of a commercial operation chosen as a representative from the Milas region, the most densely populated aquaculture area in Türkiye. Through molecular-level analyses, the health status of the European sea bass (*Dicentrarchus labrax*) was comprehensively assessed.

## Material and Methods

To examine health-related gene expression in European sea bass across seasons, samples were collected quarterly from cages in August, November, February, and June during 2023–2024. Fish were sourced from Gümüşdoğa company's cages in Kıyıkışlacık (Milas, Muğla, Türkiye). Fish of similar weights (~80-120 g) were selected to reduce sampling variability. Twenty-four fish were randomly sampled under anesthesia, with 12 from two cages per season (n=12, N=24 fish/season). Liver tissues from 12 fish, 6 from each cage, were analyzed per season (n=6, N=12 fish/season). Total RNA was extracted from liver using TRIzol reagent (Thermo Fisher Scientific) following manufacturer's guidelines. GAPDH served as the reference gene. Expression levels were assessed using the $2^{-\Delta\Delta Ct}$ method, based on threshold cycle (Ct) values. Gene expression differences were analyzed using Duncan's test and Kruskal Wallis with Mann–Whitney U tests for homogeneous and inhomogeneous data. Data are reported as mean ± standard error, with significance at $P<0.05$.

**Table 1.** Seasonal variation in some health-related gene expressions in liver tissues in European sea bass. Values are represented as mean and standard error. Data with different letters are significantly different among seasons ($P < 0.05$).

| | Seasons | | | |
|---|---|---|---|---|
| **Genes** | **Spring** | **Summer** | **Autumn** | **Winter** |
| Hepcidin | $2.44 \pm 0.78^{A}$ | $0.85 \pm 0.54^{B}$ | $0.45 \pm 0.14^{B}$ | $1.45 \pm 0.26^{A}$ |
| HSP70 | $1.65 \pm 0.47^{A}$ | $0.20 \pm 0.12^{B}$ | $0.15 \pm 0.06^{B}$ | $0.51 \pm 0.08^{A}$ |
| HSP90 | $1.76 \pm 0.52^{A}$ | $0.48 \pm 0.32^{B}$ | $0.25 \pm 0.07^{B}$ | $0.77 \pm 0.20^{A}$ |
| SOD | 2.02 ± 0.84 | 1.27 ± 0.74 | 0.86 ± 0.27 | 2.01 ±0 .38 |
| CAT | 1.13 ± 0.16 | 1.02 ± 0.15 | 0.55 ± 0.05 | 0.90 ± 0.25 |
| GPX | $2.30 \pm 0.69^{A}$ | $0.51 \pm 0.32^{B}$ | $0.32 \pm 0.11^{B}$ | $1.07 \pm 0.20^{A}$ |
| DCNT | 1.25 ± 0.39 | 0.34 ± 0.11 | 0.25 ± 0.07 | 0.66 ± 0.24 |
| CAS8 | $1.85 \pm 0.53^{A}$ | $0.12 \pm 0.03^{B}$ | $0.19 \pm 0.06^{B}$ | $0.76 \pm 0.17^{A}$ |
| CAS9 | $2.19 \pm 0.65^{A}$ | $0.27 \pm 0.08^{B}$ | $0.47 \pm 0.16^{B}$ | $1.55 \pm 0.27^{A}$ |
| IGF1 | $1.79 \pm 0.56^{A}$ | $0.14 \pm 0.09^{B}$ | $0.07 \pm 0.02^{B}$ | $0.47 \pm 0.13^{A}$ |
| IGF2 | $2.44 \pm 0.74^{A}$ | $0.30 \pm 0.21^{B}$ | $0.17 \pm 0.05^{B}$ | $0.81 \pm 0.29^{A}$ |
| GH | $1.40 \pm 0.44^{A}$ | $0.27 \pm 0.18^{B}$ | $0.14 \pm 0.05^{B}$ | $0.64 \pm 0.17^{A}$ |

*(Continued on next page)*

**Results**

Our findings indicate that the expression levels of IGF1, IGF2, and GH genes were notably elevated during the spring and winter months compared to the summer and autumn (P < 0.05). Similarly, hepcidin gene expression was significantly higher in spring and winter than in summer and autumn ($P<0.05$). In contrast, no seasonal variation was detected in the expression of the DCNT gene ($P>0.05$). Additionally, there was no significant seasonal difference in the expression of SOD and CAT genes ($P>0.05$). However, GPX gene expression was more pronounced in spring and winter than in summer and autumn ($P<0.05$). It was also noted that the expression levels of HSP70 and HSP90 were significantly greater in spring and winter compared to summer and autumn ($P<0.05$). Likewise, CAS8 and CAS9 gene expressions were significantly higher in spring and winter than in the summer and autumn months ($P<0.05$). All data are presented in Table 1.

**Discussion**

The study's results revealed that the genes associated with growth, such as GH, IGF1, and IGF2; the antimicrobial peptide hepcidin; the antioxidant enzyme GPX; stress-related genes HSP70 and HSP90; and apoptosis-related genes CAS8 and CAS9, were highly expressed during spring and winter. The data clearly indicate that fish health deteriorates in these seasons. This is believed to be linked to alterations in water quality parameters, particularly temperature. For instance, it is known that the thermocline layer in the Aegean Sea shifts in spring, leading to fish experiencing sudden temperature changes along the cage column. This scenario suggests that temperature fluctuations directly or indirectly induce stress in fish, making them more susceptible to diseases. Conducting more detailed research based on this information will enhance aquaculture efficiency and aid in developing various strategies for these specific seasons.

**Introduction**
Vitamin C and cobalt are essential micronutrients for aquatic animal health. Vitamin C boosts immunity and growth, requiring dietary intake in most fish (Gouda *et al*., 2020). Hematological assessments are vital for fish health monitoring. Cobalt, as a coenzyme, supports vit $B_{12}$ synthesis, crucial for metabolism and preventing anemia. Limited studies exist on combined effects of vit C and cobalt in sturgeon (Li *et al*., 2022). This study examines their combined effects on hematological indices in Siberian sturgeon.

**Materials and Methods**
270 juvenile Siberian sturgeon were reared for 12 weeks in 27 tanks, using a factorial design with $CoCl_2$ (2, 4 mg/kg) and vit C (200, 800 mg/kg). Blood samples were collected and analyzed for RBC, WBC, differential leukocytes, Hb (cyanmethemoglobin method), HCT. Data were analyzed by two way-ANOVA and Duncan's test (SPSS).

**Results**
The results of the blood indices showed that the inclusion of 800 mg of vit C per kg of diet significantly increased the white blood cell count compared to the control and other treatment groups. The control group exhibited the lowest white blood cell count ($p < 0.05$). Additionally, the levels of RBC, Hb, and Hct in fish fed a diet that included a combination of 2 mg of $CoCl_2$ and 200 mg of vit C were significantly higher than those in the other treatments and the control group.

**Discussion**
In the present study, the addition of $CoCl_2$ and vit C to the diet of Siberian sturgeon significantly improved hematological indices. Given that hematological indices are crucial measures for assessing fish physiological health, this study observed significant changes in the number of WBCs, RBCs, Hb, Hct, and differential leukocytes. Specifically, the number of WBCs and RBCs increased in the treatments containing these substances, with the highest levels of WBCs observed in the 800 mg/kg vit C treatment and the highest levels of RBCs in the 2 mg/kg $CoCl_2$ + 200 mg/kg vit C treatment. This increase indicates a positive effect of these substances on hematopoiesis and the strengthening of the fish's immune system. These effects are attributed to the role of cobalt chloride in the synthesis of vit $B_{12}$ (Tonye & Sikoki, 2014) and the role of vit C in iron absorption and erythropoiesis (Garcia et al., 2007). Vitamin $B_{12}$ aids in hematopoiesis by increasing the production and maturation of RBCs, while vit C facilitates iron release from the liver and improves its absorption (Hall & Hall, 2020). These results are consistent with previous studies on the effects of these substances on hematological indices in other fish species (Makwinja & Geremew, 2020). Furthermore, the 2 mg/kg $CoCl_2$ + 200 mg/kg vit C treatment increased Hb and Hct, indicating improved oxygen-carrying capacity. Micronutrient deficiencies can lead to anemia (Brunt & Austin, 2005). The increase in Hb/Hct is associated with ferritin release by vit C, although Hb changes may also stem from osmotic stress. Vitamin C enhances iron absorption. Differences from other studies (Narra et al., 2015) may be species-specific. These findings highlight the complex role of vit C and $CoCl_2$ in the hematology and health of Siberian sturgeon.

Hematological indices in *Acipenser baerii*, fed diets containing cobalt chloride and vitamin C after 12 weeks.
Significant difference $p < 0.05$ are indicated by non-synonymous letters, and asterisks (*) denote significant interaction effects $p < 0.05$.

# BENTHIC DIVERSITY CHARACTERIZATION OF THE PIEDRAS RIVER: BASIS FOR THE RECOVERY OF THE CARPET SHELL (*Ruditapes decussatus* Linnaeus, 1758)

J. D. Escobar*, P. Ruiz-Azcona, O. Moreno and M. Herrera

IFAPA Agua del Pino
21459 Cartaya
Huelva, Spain
E-mail: josed.escobar@juntadeandalucia.es

Introduction

The MOLUSOS project aims to revitalise bivalve aquaculture and restore natural populations of the carpet shell clam (*R. decussatus*) in the estuary of the Piedras River (Huelva, SW Spain), where this species has experienced a pronounced decline in recent decades, possibly associated with overfishing, the expansion of the recreational boating fleet, and habitat degradation. To achieve this goal, three strategies have been proposed: (1) study of the current benthic fauna and sediment conditions in the Piedras River; (2) establishment of a broodstock sanctuary within the estuary; and (3) monitoring of *R. decussatus* populations to assess the effects of the sanctuary. The project is currently in its first phase.

This study is being conducted to characterise benthic diversity in the Piedras River estuary and to establish a baseline for restoration actions targeting *R. decussatus.*

Materials and Methods

In this initial phase, a baseline survey of the benthic fauna of the Piedras River was conducted, comprising 38 sampling stations distributed along a 12 km stretch of the river. Sampling was performed using a boat-towed dredge. The study area encompassed four estuarine sectors that have historically supported *R. decussatus* populations: San Miguel (SM), with 12 stations distributed between the main channel (R) and the shore (V); Casa del Palo (CP), with 14 stations across the channel and shore; La Chanca (CH), with 7 stations located in the channel; and Tartesos (T), with 5 channel stations. At each station, three replicates were collected and the species and/or morphotypes present were identified taxonomically. Descriptive analyses were performed in Microsoft Excel, while diversity indices (Shannon–Wiener, Simpson, and species richness), similarity analyses—including NMDS (Non-metric Multidimensional Scaling) based on the Bray–Curtis index and Multilevel Pattern Analysis were conducted in R software.

Results

Data from the SM, CP and T sectors were processed and analysed, yielding species and morphotype abundances (ind/m$^2$), diversity indices for each sector (Table 1), and relative composition (%) by taxonomic group, as well as the proportion of molluscs and commercial bivalves identified (Table 2).

The similarity analysis (Figure 1) revealed three main groupings among sampling stations, identified through NMDS and assessed using the Silhouette index. In addition, the indicator index for each species was estimated for each group, which made it possible to determine their characteristic species: Group 1 dominated mainly by *C. glaucum* and *R. decussatus* as highly indicative species (IndVal > 0.95, p < 0.005); Group 2 represented exclusively by *S. solida* and *V. verrucos*a as indicator species (IndVal = 0.723, p <0.05); and Group 3 represented mainly by *Parvicardium exiguum*, *Tritia reticulata* and *Abra alba* (IndVal >0.95, p<0.005).

**Discussion**

The results indicate that SM-V exhibited the highest diversity and species richness, together with a more even distribution of abundances. CP showed intermediate values, with a slight reduction in CP-R compared to CP-V. In contrast, T recorded the lowest diversity and richness, with a marked dominance of a few species. These differences highlight a significant variation in benthic community structure among sectors, likely associated with local environmental factors (e.g., substrate quality, hydrodynamics, anthropogenic pressure). Overall, the findings suggest that SM provides more favourable conditions for sustaining diverse and even benthic communities, whereas T offers an environment that supports more simplified communities dominated by a few species.

# TRANSCRIPTOMIC PROFILING OF FOLLICULAR CELLS ACROSS THE ANNUAL REPRODUCTIVE CYCLE IN EUROPEAN SEA BASS *Dicentrarchus labrax*

Amanda Escorza [1]*, Cinta Zapater[1], Alessia Mascoli[1], Sol Ibañez[1], Gregorio Molés[1], Ana Gómez [1]

[1] Department of Fish Physiology and Biotechnology
Instituto de Acuicultura Torre de la Sal (CSIC)
12595 Ribera de Cabanes
Castellón, Spain
E-mail: amanda.escorza@.csic.es

## Introduction

Reproductive control and prevention of precocious puberty are key for sustainable aquaculture. The European sea bass (*D. labrax*) is economically important in the Mediterranean, yet the molecular regulation of its oogenesis remains incompletely understood. Oocyte development involves systemic hormonal cues (FSH, LH, sex steroids) (1) and local paracrine signals within the ovarian follicle, between the oocyte and surrounding granulosa cells (2). Follicular cells support oocyte growth and maturation, and coordinate folliculogenesis through specific signaling pathways (3). This study aimed to investigate seasonal changes in gene expression in follicular cells over a full reproductive cycle to identify the molecular mechanisms driving follicular development (4)

## Materials and methods

Follicular cells were isolated throughout the annual cycle from ovaries of adult females kept under natural photoperiod and temperature at the Instituto de Acuicultura Torre de la Sal (IATS), following Crespo *et al*. (5). Ovaries were dissected, washed, and dissociated in M199:$H_2O$ medium with antibiotics. Enzymatic digestion was performed with trypsin (37 °C, 30 min), followed by filtration (100 µm), centrifugation, and resuspension in M199 Hanks medium. Follicular cells were counted using Trypan blue in a Neubauer chamber. RNA was extracted with the Maxwell® LEV simplyRNA Tissue kit, and quality was assessed with Nanodrop® and Bioanalyzer. Libraries were prepared and sequenced (Illumina NovaSeq X) by BMKgene.

## Results

A total of 67 genes involved in steroid hormone biosynthesis were identified. The highest number of differentially expressed steroidogenic genes occurred in spring/summer versus winter, with 13 and 15 DEGs (mostly upregulated), respectively. These data highlight dynamic seasonal regulation of gene expression in follicular cells, particularly in relation to steroidogenesis and follicle development.

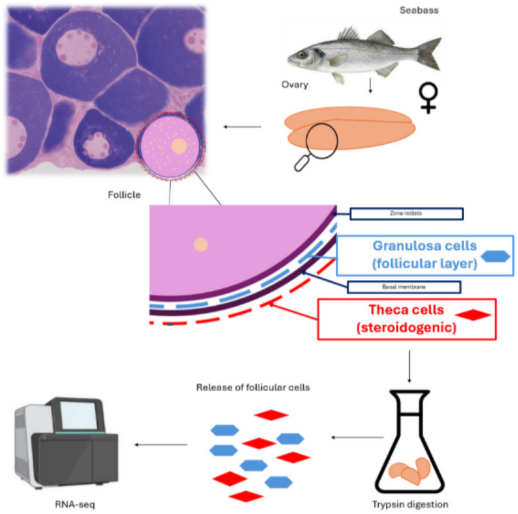

**Figure 1.** Graphic summary of the methodology used

*(Continued on next page)*

Transcriptomic profiles were compared using RNA-seq of follicular cells isolated from female European sea bass ovaries collected during the four seasons (summer, autumn, winter, and spring). Ovarian staging was performed by histological analysis of each ovary and classified as previtelogenic, vitelogenic, maturing/ovulating and atresic. Major transcriptional changes were observed between late winter (end of the spawning period) and summer (post-spawning), coinciding with follicular atresia and initiation of new follicle formation, so many of these differentially expressed genes are probably related to folliculogenesis. A second transcriptional shift was noted at the onset of vitelogenesis respect to the previtelogenic stage, while few changes occur during the secondary growth from initial vitellogenesis to postvitellogenesis / maturation. A total of 67 genes involved in steroid hormone biosynthesis were identified. The highest number of differentially expressed steroidogenic genes occurred in spring/summer (previtelogenesis) versus winter (spawning), with 13 and 15 differentially expressed steroidogenic genes (mostly upregulated), respectively. These data highlight dynamic seasonal regulation of gene expression in follicular cells, particularly in relation to steroidogenesis and follicle development.

**Discussion and Conclusion**

Transcriptomic analysis of follicular cells revealed two main peaks of gene expression. An increase in gene expression activity after the spawning period (late spring / summer), likely related to tissue remodeling and folliculogenesis (7). Another peak in gene expression upregulation could be observed in winter, at the beginning of the spawning phase. This last pattern aligns with previous findings on key reproductive genes (*fshr, lhr, star, cyp19a1a*) during winter in European sea bass ovaries (6). Among steroidogenic genes, *cyp11a1.2* and *hsd3b1* were consistently upregulated across seasons. In conclusion, these results demonstrate that follicular cell transcriptional activity in *D. labrax* is seasonally regulated, contributing to the understanding of ovarian development and informing improved reproductive strategies in aquaculture.

# THE DETECTION AND INTAKE OF INERT MICRODIETS BY LARVAL FISH IS PREDOMINATED BY SENSORY STIMULI RATHER THAN VISUAL STIMULI: A PROOF-OF-CONCEPT STUDY

Espinal, C*; Vrij, M; Bisperink, C.; Fransen, H.

Processus BV - Hoogven 16
5469 EM, Erp, Netherlands
Email: carlos@aquasnow.nl

**Introduction**
Early-stage fish larvae are widely assumed to rely primarily on visual cues such as contrast, movement, and shape to identify and capture prey like Artemia or rotifers. This perception has historically limited the use of inert microdiets in early feeding regimes. However, fish larvae possess multiple sensory modalities. In this proof-of-concept study, we explored whether marine larvae are able to detect and ingest inert feed pellets lacking conventional visual triggers.

**Methods**
We conducted exploratory trials with larvae of D. Labrax, S. Aurata, Pseudochromis spp. AquaSnow inert microdiet particles with low visual contrast and no movement were introduced into controlled tanks. Behavioural responses were recorded on video, with attention to swimming patterns, feed detection, and ingestion. No formal statistical analysis was conducted; the aim was to qualitatively assess whether larvae would actively seek out and consume the inert particles.

**Results**
Larvae across all tested species were observed to actively approach, chase, and ingest microdiet particles. This behaviour occurred consistently despite the absence of visually stimulating cues such as movement. The responses suggest that sensory modalities in addition to vision—potentially chemical (olfactory) cues—may play a role in early-stage feed detection.

**Discussion**
Our findings challenge the prevailing assumption that visual cues are essential for initiating feeding behaviour in fish larvae. While preliminary, the observations support the idea that odor or chemical leaching from microdiets may help trigger feeding responses in marine larvae. If confirmed, this opens new possibilities for microdiet formulation, particularly in enhancing palatability through targeted chemoattractants.

**Conclusion**
This exploratory study provides early evidence that marine fish larvae can detect and consume inert microdiets even in the absence of strong visual stimuli. Further research is needed to understand the specific sensory mechanisms involved, but these results point to the importance of considering olfactory cues in larval feed design.

# ACUSTO-OPTIC INTEGRATED SYSTEM FOR BLUEFIN TUNA *Thunnus thynnus* BIOMETRICS

Víctor Espinosa[1], Sergio Morell-Monzó[1], Vicente Puig-Pons[1], Anderson Ladino-Velásquez[1], Joaquín Martínez-Peiró[2], Pau Muñoz-Benavent[2], Gabriela Andreu-García[2], A. Ortega[3], P. Baixauli[3], F. de la Gándara[3], and Isabel Pérez-Arjona [1]

[2] Instituto de Automática e Informática industrial (ai2), Universitat Politècnica de València, Campus de Vera, (Spain)
[3] Instituto Español de Oceanografía IEO-CSIC) Planta de Cultivos Marinos. Carretera de la Azohía s/n. 3086. Puerto de Mazarrón (Spain)

**Introduction**

We present preliminary results of the integration of a stereocamera and a high frequency sweeping echosounder designed to obtain biometric measurements of free swimming bluefin tuna (*Thunnus thynnus*). The stereovideo recordings can be analysed in a full automated way with the software AUTOTUNA (R) to obtain length and height of tuna. The echograms are inspected for the fishes located in the axis of the system by the 3D stereo measurement, in order to extract their lateral dimensions from echo characteristics. The three obtained fish dimensions (length, height and width) can improve the biomass estimation through multidimensional biometric relationships.

**Materials and methods**

We have integrated a S500 multipurpose single beam echosounder produced by Cerulean and a stereoscopic videocamera built by Chrome Motion Electronics (https://www.chromemotion.es/). The S500 implements chirped modulation, which sends a varying frequency ultrasonic pulse. The advantages of chirp include better signal to noise ratio, and much higher range resolution than non-chirp devices. The S500 can report a simple distance measurement or can provide raw signal strength data profiles for advanced analysis (https://ceruleansonar.com/product/sounder-s500/).

The S500 uses a high frequency 500kHz transducer giving about 5° beam width and it has a measurement range of over 100m that exceeds sufficiently the measuring range of the stereocameras, limited by visibility and precision up to 10 m. It includes three communication interfaces: Ethernet (100Mb/sec), USB (12Mb/sec), and 3.3-5.0V serial (115kbaud). The echosounder transducer is placed in the middle of the pair of stereocameras defining with its acoustical beam, the synchronised acousto-optic observation axis (Figure1). A Python based software has been developed to get the raw signal data profile of the S500.

The stereo video recordings can be analysed in a full automated way with the software AUTOTUNA (R) to obtain length and height of tuna. The echograms are inspected for the fishes located in the axis of the system by the 3D stereo measurement, in order to extract their lateral dimensions from echo characteristics. The three obtained fish dimensions (length, height and width) can improve the biomass estimation through multidimensional biometric relationships.

**Results**

The system has been tested at the ICAR-IEO and it is currently recording periodically the growing of second year individuals. Figure 2 shows the histogram of 273 length measurements automatically obtained in a 19 minute recording, and an example of corresponding echogram ping envelope and image recording.

We are developing criteria for fish width measurement from the temporal recording of the central ping in each fish trace in the echogram, using calibrated targets.

*(Continued on next page)*

Figure 1. Left: Stereoscopic videocamera and synchronised S500 echosounder developed by the UPV and Chrome Motion Electronics. Right: system deployed at the ICAR tanks; the stereo pair is set vertically for the horizontally swimming tuna.

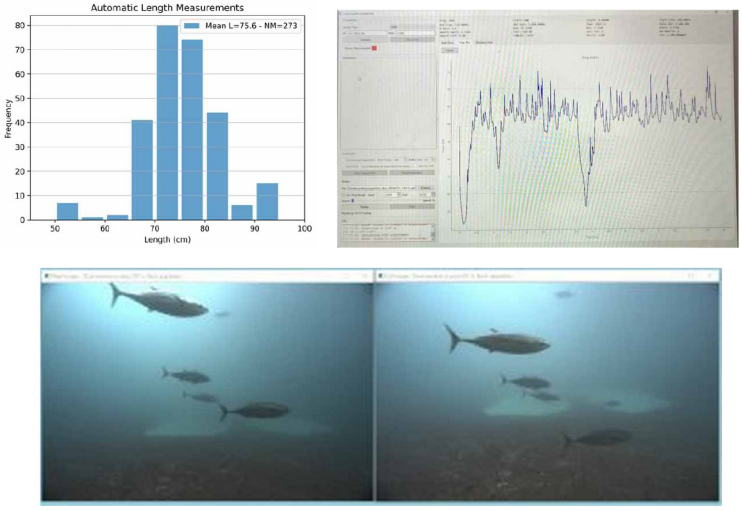

Figure 2. Upper panel left: Stereoscopic videocamera measurements of BFT furcal length distribution. Upper panel right: example of temporal characteristics of a ping of the S500 echogram, showing fish echoes at 1 m and 3.8 m from the transducer. Lower panel: stereoscopic pair of images.

## Discussion and conclusion

We have developed an integrated hardware and software solution for the synchronised use of a stereoscopic camera and a chirped echosounder for the obtention of biometric information of free-swimming tuna in tanks, cages or transfers in purse seiner operations. The system offers the possibility of obtaining 3D information of tuna shape to adjust biometric models for weight estimation (Puig *et al.* 2018).

## Introduction

Over the past decades, global consumption of aquatic animal products has grown at a faster pace than the world's population. While capture fisheries have largely stabilized, aquaculture has emerged as the fastest-growing food production sector, representing more than half of global aquatic animal production since 2022. In the Mediterranean, marine aquaculture has expanded steadily, becoming a key economic sector and research field. Nevertheless, the sector faces challenges related to environmental sustainability, animal welfare, and disease control under intensive production. Advances in technology are critical to achieving the 'blue transformation' proposed by the FAO, with cost-effective monitoring systems playing a central role in sustainable management.

## Materials and Methods

We developed a stand-alone acoustic monitoring system integrating active and passive sensors for installation on floating aquaculture cages. The system comprises four modules: a solar-powered energy module with $LiFePO_4$ battery storage and MPPT charge control, a communication module providing remote access via a 4G router and TeamViewer for real-time configuration and data visualization, an acquisition unit equipped with a sound card, a mini pc (Linux or Windows-based) and a echosunder (Kongsberg WBT Mini, split-beam, 120 kHz; and Zunibal ZSR, single-beam, 120 kHz) two acoustic sensor a an Aquarian H2a hydrophone and a 120 kHz echosounder transducer (single-beam or split beam depending the chosen echosounder) that can be seen in Fgure 1 (a,b, c, d).

The hydrophone system records continuous or scheduled soundscape data using Linux or Windows-based acquisition software, while the echosounders acquire fish biomass, growth, and behaviour data. Calibration procedures were performed for both hydrophone and echosounders following standard target and reference hydrophone methods.

## Results

Hydrophone calibration in a controlled tank environment showed frequency-dependent sensitivity, with an increasing trend between 125 Hz and 4 kHz, followed by a decrease at higher frequencies. Echosounder calibration confirmed correct target strength measurements for both devices, with the scientific unit offering higher resolution but at the cost of greater storage requirements.

Field tests were conducted in a 5 m diameter fish cage located at Gandia harbour. Echograms from both echosounders showed clear detection of targets at multiple depths, validating system performance. The Kongsberg WBT Mini produced higher-definition data, while the Zunibal ZSR provided adequate quality with reduced data storage needs.

## Discussion and Conclusions

The proposed system demonstrated the feasibility of integrating low-cost active and passive acoustic monitoring in a fully autonomous platform for aquaculture. The modular design enables flexible sensor integration, while solar power and remote communication enhance operational autonomy. Preliminary results confirm that both high-end and commercial echosounders can provide useful data for fish and feeding monitoring (Soliveres et al 2017, Llorens et al. 2021) , with trade-offs between resolution and storage requirements. This approach represents a step toward cost-effective, scalable monitoring solutions for sustainable aquaculture.

# COMPARATIVE IMMUNE ASSESSMENT IN SKIN MUCUS AND HEMOLYMPH OF THE CUTTLEFISH *Sepia officinalis*.

P. Espinosa-Abellán[1*], M. Velázquez-Abengochea[1], M.L Morenilla-Fernández[1], J. Cerezo-Valverde[1], M. Pérez-Marcos[1] and C. Espinosa-Ruiz[1,2]

**Introduction**

The immune system of *Sepia officinalis* is primarily innate, relying on various cellular and humoral components to defend against pathogens (Benois et al., 2020). The main immune cells are haemocytes, which are involved in pathogen response and detoxification. The white body (WB) in cuttlefish plays a crucial role in haematopoiesis, producing haemocytes that are essential for immune responses. Additionally, the cuttlefish's haemolymph and mucus contain various immune-related enzymes and proteins that contribute to its defence mechanisms (Le Pabic et al., 2014). While the innate immune system of *Sepia officinalis* is well-adapted to its environment, it lacks the adaptive immune components found in vertebrates (Beuerlein et al., 2002). This reliance on innate mechanisms highlights the evolutionary divergence in immune strategies between invertebrates and vertebrates. The study of cephalopod immune systems, such as that of *Sepia officinalis*, provides valuable insights into the evolution of immune functions and the potential for discovering novel immune-related molecules.

**Material and Methods**

Eight male cuttlefish specimens were kept in the facilities of the marine resources centre at the IMIDA (Murcia, Spain). The study animals were fed at 1.5% of body weight daily for 1 month. Samples of skin mucus and haemolymph were obtained from each specimen. Different immune-related parameters were evaluated in the samples. The total content of protein was evaluated in both serum and skin mucus (Bradford, M., 1976), as well the protease and antiprotease activities were determined (Ross N.W. et al., 2000). Besides, the number of haemocytes was recounted and the hemocyanin concentration in the haemolymph was evaluated.

**Results and discussion**

Immune parameters were successfully quantified in both skin mucus and haemolymph samples of *Sepia officinalis*, allowing for a preliminary characterization and standardization of baseline immune profiles in this species.

The concentration of proteins in haemolymph was more than fivefold greater than that quantified in skin mucus, which appears to be consistent with the composition of haemolymph. The haemolymph functions as a medium for the conveyance of haemocytes, nutrients, gases, and metabolic byproducts, thereby clarifying the difference with the skin mucus, which solely comprises various molecules predominantly associated with immune-related functions (Castillo M.G. et al., 2015). The protease activity in haemolymph is virtually negligible; however, in skin mucus, it constitutes approximately 7% of protease activity. Correspondingly, the antiprotease activity in skin mucus significantly surpasses that observed in haemolymph, nearly doubling it (29% in the haemolymph and 46% in the skin mucus).

Statistical analysis revealed significant differences between both tissues ($p < 0.05$) for protein concentration, protease and antiprotease activities among others, suggested functional compartmentalization of immune responses in *S. officinalis*. These results represent an integrated reference values for humoral and cellular immunity in cuttlefish, providing a foundation for future studies in cephalopod health monitoring and aquaculture applications.

## Introduction

The gilthead seabream (*Sparus aurata*) is a significant species in Mediterranean aquaculture, and its production is often challenged by various stressors that can impact fish welfare and productivity. Stress in aquaculture can arise from environmental factors, handling, and parasitic infections, leading to physiological and metabolic changes in the fish. Acute handling stress has been shown to increase blood glucose and lactate levels, as well as alter haematological profiles, indicating a physiological stress response that can affect fish welfare and product quality (Fazio et al., 2015). The use of silkworm pupae as an alternative protein source in aquaculture is being explored to replace traditional fishmeal, which is costly and often sourced from outside regions. Sericin administration has been shown to decrease serum corticosterone levels and enhance antioxidant defences in the hippocampus, reducing apoptosis and heat-shock protein levels (Mahmoudi et al., 2021). These effects indicate that sericin can modulate stress responses at the molecular level, potentially benefiting fish under stress. The integration of sericin into aquaculture practices could help manage stress in fish, particularly during critical stages such as larval development, where sensitivity to stress is higher (Jawad, 2021). By reducing stress, sericin could improve growth rates, health, and survival rates in aquaculture systems.

## Material and Methods

Forty-four specimens from gilthead seabream *Sparus aurata* were randomly disposed into eight RAS tanks. The daily feeding rate was adjusted to 3% and introduced two times per day. The animals fed for 30 days with the following diets: a control diet and supplemented diet with 1% of silkworm chrysalis (D1). Besides, the half fish from each diet group were subjected to chronic stress, according to a previously described protocol (Cámara-Ruiz, M. et al 2022). Briefly, stressed fish were subjected to 1 min air exposure twice a week for 4 weeks. Fish samples of skin mucus and blood were obtained after 15 and 30 days of feeding, six sample were randomly selected from each aquarium. Immuno-related parameters were measured in the mucus and serum (protein levels, protease and antiprotease activities). All the samples were analysed per triplicate.

## Results and discussion

At 15 days, our results indicated that stressed animals showed a slightly lower weight gain (WG) and specific growth rate (SGR) than the animals fed the control diet. The fish fed D1 showed similar WG and SGR to the control animals. However, those animals fed D1+stress showed a significant increase in WG and SGR with respect to stressed fish. At 30 days, stressed animals showed a significant decrease on WG and SGR with respect to control groups. However, no differences with control group were observed on WG and SGR from animals fed the D1 or D1+stress with respect to control group. Supplementing *Bombyx mori* pupae appears to reduce the negative effects of stress on growth, which is consistent with reported for other species, where protein substitutions from silkworm pupae meal of (10-60%) have been carried out with good results without compromising the health of the fish (Nazerath Nisha, S. et al., 2014; Shakoori, M. et al., 2016).

Protein, protease, and antiprotease activities were assessed in skin mucus and serum. No significant differences in protein levels were detected in mucus or serum at 15 days, nor in serum from stressed fish at 30 days, consistent with previous findings (Cámara-Ruiz et al., 2022). However, fish fed the D1 diet showed reduced serum protein at 30 days compared to controls, suggesting an effect on mucus immunity despite no weight loss. In skin mucus, stressed fish fed D1 also exhibited a significant protein decrease.

*(Continued on next page)*

At 15 days, no differences in mucus antiprotease activity were observed among groups. By 30 days, D1-fed fish showed higher mucus antiprotease levels than controls, with stressed D1-fed fish exhibiting the highest values. This suggests D1 enhances mucus defence in both stressed and non-stressed fish, consistent with reports that Bombyx mori pupae protein supports fish health (Shakoori et al., 2016). Serum antiprotease activity was also elevated in all groups compared to controls, indicating responses to both diet and stress, with stressed D1-fed fish showing the greatest improvement.

For protease activity, serum levels increased at 15 days with D1 but returned to baseline at 30 days. In mucus, D1-fed fish showed decreased activity at 15 days followed by a rebound at 30 days. Stressed fish were unaffected, except when fed D1, which significantly increased mucus protease, suggesting enhanced immune defence.

Our findings demonstrate that a 30-day dietary supplementation with *Bombyx mori* pupae significantly enhanced growth performance and non-specific immune defenses in gilthead seabream (*Sparus aurata*) subjected to chronic stress. These results highlight the potential of *B. mori* pupae as a functional dietary ingredient (even at 1%) to improve resilience and overall health in aquaculture species under challenging farming conditions.

## Introduction

Gilthead sea bream (*Sparus aurata*) is extensively cultivated in the Mediterranean due to its economic significance and its adaptability to diverse aquaculture systems. Despite major advances, challenges remain in nutritional management and prevention of metabolic diseases in sea bream farming (Hallerman et al., 2022). The liver plays a crucial role in fish metabolism by regulating lipid mobilization under nutritional stress. Diet composition, particularly fatty acid type and quantity, impacts liver function, energy balance, and disease resistance. High lipid diets may induce to hepatic steatosis, which in turn impairs liver function and triggers inflammation, fibrosis, and metabolic disorders. In sea bream, steatosis negatively influences growth, feed efficiency, and infection resistance, potentially leading to increased mortality and decreased product quality, thereby affecting aquaculture profitability (Oliva-Teles, 2012; Turchini et al., 2009). Understanding differential gene expression is essential to elucidate how lipid-rich diets disrupt lipid homeostasis, and promote fatty liver. Integrating transcriptomic methodologies with novel nutritional approaches is vital for improving fish health and fostering sustainability in aquaculture (Asaoka et al., 2014; Costa-Silva et al., 2017). Consequently, the objective of this study was to assess hepatic gene expression changes in gilthead seabream on a fish fed a fish-oil-enriched diet.

## Material and Methods

Juvenile sea bream (*S. aurata*) with an average weight of 10-14 g were kept in the facilities of the experimental animal service (SEA) at the University of Murcia (UMU). The study animals were fed at 1.5% of body weight daily for 3 months with the following diets (two replicates): i) standard diet (Skretting, Control Group), ii) diet enriched with 10% fish oil (Fish oil Group). At the end of the experiment, the fish were sacrificed (n = 6 per group), the liver was obtained and frozen in liquid nitrogen. Total RNA was extracted from the liver and its integrity was verified, analysing its profile with a bioanalyser. cDNA library construction was carried out using the Illumina Stranded mRNA Prep' protocol. The libraries were sequenced using a 2 x 100 bp paired-end sequencing strategy, with a minimum sequencing depth of 25 million pairs of reads (50 million individual reads) per sample using the NextSeq 2000 sequencer (Illumina, USA). In silico differential expression analysis was carried out using Rstudio 4.3.0 software.

## Results and discussion

A total of 385,292,118 reads were obtained from 12 cDNA libraries (380,669,063 clean reads). From these clean reads, expression counts were obtained for a total of 32,008 genes, according to the available genomic annotation. So, 463 significantly differentially expressed genes were identified, of which 158 were found to be up-regulated and 305 down-regulated.

Taken together, our data confirm the existence of a specific transcriptional response associated with fish oil consumption. Up-regulated genes were clustered in categories linked to transport activities, hydrolase and oxidoreductase enzymes, whereas genes involved in triglyceride-lipasa activity were prominently down-regulated. Enrichment analysis highlighted oxygen binding, haemoglobin binding and olfactory receptor binding together with RNA-binding, ligase and glycosyl-transferase activities, suggesting a complex physiological response to treatment. In contrast, functions linked to the transport of organic ions and anions were suppressed. These results highlight the modulation of key functions in cell metabolism and signalling in response to fish oil treatment.

*(Continued on next page)*

The Peroxisome Proliferator-Activated Receptor (PPAR) signalling pathway was significantly over-represented among the differentially expressed genes., coherently linking the transcriptional response to lipid metabolism, energy balance and inflammation. This is consistent with a possible physiological effect related to the treatment administered, especially if associated with nutritional intervention or lipophilic compounds such as fatty acids (Antonopoulou et al., 2017). The most prominent pathway was 'Ribosome biogenesis in eukaryotes', ($p<0.0029$) and a Gene Ratio higher than 0.46. The 'One carbon pool by folate' pathway exhibited significance, albeit to a lesser extent. These findings suggest a potential reconfiguration of ribosomal components and basic cellular metabolism, possibly linked to a specific physiological response induced by the high fatty acid diet employed in this study. (Colombo, 2020).

Overall, these findings elucidate the molecular mechanisms by which high fatty acid diets influence liver health in gilthead seabream. The identification of specific genes and pathways associated with dietary response lays a foundation for optimizing dietary formulations in Mediterranean aquaculture, enhancing the health, welfare, and production efficiency of this important species.

# MULTIOMICS OF EUROPEAN SEABASS (*Dicentrarchus labrax*) EXPOSED TO ACUTE STRESS BY TRANSPORT

Gonçalo Espregueira Themudo*[1], Bruno Reis[1], Felipe Schoninger[1], Francisco Cunha[1], Christopher Pimentel[1], Paula Simó-Mirabet[2], Juan A. Martos-Sitcha[2], and Benjamin Costas[1]

1 - CIIMAR / UP - Centro Interdisciplinar de Investigação Marinha e Ambiental, Universidade do Porto, Matosinhos, Portugal
2 – Universidad de Cádiz, Cadiz, Spain
Address: Terminal de Cruzeiros do Porto de Leixões, Av. General Norton de Matos, 4450-208 Matosinhos, Portugal
email: gthemudo@ciimar.up.pt

**Background**
Unravelling new knowledge on biomolecular response to acute stress in farmed fish is essential for better monitoring, improve animal welfare and health, and reduce mortality. This study aimed to evaluate physiologic and metabolic effects of acute stress induced by transport in European seabass (*Dicentrarchus labrax*). Trials were conducted at University of Cádiz facilities.

**Methods**
After acclimatisation, fish were divided in four groups of fish. One of the groups was immediately sampled to serve as a non-stressed initial control. Two groups of fish were transferred each to three oxygen saturated containers and transported by a transport van for 4 hours. Upon arrival, half were immediately sampled while the remaining fish were put in the original system and sampled at 24h post-arrival as recovery group (n=12 per sampling time). A fourth group was kept under control conditions and sampled at 24h.

RNA-seq
Total RNA was extracted from skin tissue and pooled (n=4 samples per treatment) for RNAseq on an Illumina sequencer. Raw sequence reads were trimmed and filtered using fastp, to remove adapter sequences and low-quality reads. Transcripts were quantified using the pseudoalignment method implemented in kallisto. Differentially expressed genes (DEGs) between the different treatments and the control samples were determined using DESEQ2.

Proteomics
Skin mucus samples from the same fish were processed for proteomic analysis following the solid-phase-enhanced sample preparation protocol and digested with Trypsin/LysC enzymes (Osório et al., 2021). Proteins were identified and quantified by nanoLC-MS. Raw data was processed in Proteome Discoverer v.3.0.1.27 (Thermo Scientific) and searched against the UniProt database for Eupercaria (1.1 million proteins). Protein label-free quantitation was performed with the Minora feature detector node at the processing step. Raw data hits were filtered using coverage above 30%, unique peptides above 2 and a SEQUEST HT score greater than 100.

**Results**
Data showed different genes regulated during transport induced acute stress. In addition, the European seabass transcriptome returned to base level expression by 24h (fig.1), in contrast with the proteome (fig.2). This indicates that while the effect of the stress may no longer be detectable at the gene transcript level, the physiological response continued, as peptide levels were still modulated. Further studies are needed to determine when protein levels return to base level. Gene Ontology (GO) terms upregulated in the transcriptome during stress include genes implicated in circadian rhythm (GO:0032922, GO:0007623, GO:0048511), negative regulation of cellular processes (GO:0043066, GO:0043069, GO:0048523, GO:0048519) and downregulated were genes related to nervous system development (GO:0007420, GO:0060322, GO:0007417), DNA-binding (GO:0043565, GO:0003700) and transcription (GO:0140110, GO:1903506, GO:0006355).

At the proteomic level, differentially expressed proteins are associated with GO terms regarding the activation of the immune response (GO:0002253, GO:0050778, GO:006959, GO:0002252) and wound healing/coagulation (GO:0030195, GO:0061045). These results elucidate the cascade of events that occur after acute stress in seabass. Further analysis we are working on with other species (trout and salmon), other types of stress and microRNAs will enable us to generalize these results and find common responses between species and have a more detailed view of all the processes affecting them.

**Introduction**

The Mar Menor lagoon, located in the south-east of the Iberian Peninsula, is one of the most unique coastal ecosystems in the western Mediterranean. However, in recent decades it has suffered progressive environmental degradation, mainly as a result of the intensification of agriculture in its river basin, unplanned urban development and wastewater discharges (Paredes et al., 2021; Velasco et al., 2022). These factors have favored eutrophication processes, characterized by high nutrient concentrations, phytoplankton proliferation, loss of macrophytes, episodes of anoxia and occasional ecosystem collapses, such as the one that occurred in 2016 (García-Ayllón, 2018). In response to this situation, nature-based solutions have been proposed to promote the resilience of the system and restore some of its ecological functions. Among these, the use of filter-feeding bivalves as a bioremediation tool stands out. *Ostrea edulis*, the European flat oyster, is a species with a high capacity to filter and retain particles, organic matter and phytoplankton (Pogoda et al., 2019; Bricker et al., 2020), which can contribute to improving water quality and promoting the recovery of degraded habitats. Its reintroduction or experimental cultivation in the Mar Menor could represent a complementary strategy for the functional restoration of the ecosystem. This study aims to investigate the influence of different dietary microalgae on the antioxidant activity and immune parameters in European flat oysters, with a focus on three key physiological compartments: hemocytes (cellular immunity), hemolymph and intervalvar fluid (humoral immunity). By exposing oysters to controlled microalgae diets simulating the Mar Menor ecosystem, we evaluate how species-specific algal blends modulate oxidative stress and immune defenses across these interconnected systems.

**Materials and methods**

An *in vivo* experimental trial was conducted under different dietary conditions simulating real scenarios in the Mar Menor over a 30-day period, using adult oysters (Ostrea edulis). The study aimed to evaluate their subsequent immune response and antioxidant activity. The oysters were randomly divided into three groups: a control group (fed with commercial gel phytoplankton containing 33.3% *Isochrysis* T-Iso, 31% *Nannochloropsis*, 18% *Tetraselmis*, and 18% *Phaeodactylum*) and two experimental groups fed with different microalgae cocktails prepared from selected Mar Menor strains to replicate the ecosystem's environmental conditions. The first cocktail (Cocktail 1) contained *Mayamea* sp., while the second (Cocktail 2) consisted of a mixture of *Mayamea* sp. and *Erythrolobus* sp. The microalgae were cultured under controlled conditions before being used as oyster feed.

Samples were taken from oysters on days 0, 15 and 30 of the trial. The hemolymph was extracted by puncturing the abductor muscle, and the intervalvar fluid was also obtained. The samples were centrifuged at 4°C to separate the cells and the supernatants, which were stored at -20°C until analysis.

Total antioxidant activity was determined in the microalgae used in the assay as well as in the cells obtained from hemolymph and intervalvar fluid in order to characterize the physiological responses induced by exposure to microalgae cocktails. In the supernatants of both hemolymph and interstitial fluid, soluble proteins were quantified using the Bradford colorimetric method, with bovine serum albumin (BSA) as the standard. Enzyme activities were analyzed using spectrophotometric assays: antiprotease activity was measured through trypsin inhibition; lysozyme activity was measured through the lysis of the bacterial substrate *Micrococcus lysodeikticus*; and peroxidase activity was measured through 3,3',5,5'-Tetramethylbenzidine oxidation. In addition, total antioxidant capacity was evaluated.

The experimental design allowed for analysis of temporal variation within each treatment and analysis of the differential effects between diets, as well as exploration of functional differences in immune responses between hemolymph cells and interstitial fluid cells.

*(Continued on next page)*

Statistical treatment of the data was performed using multifactorial analysis of variance (ANOVA), followed by post hoc tests (Tukey HSD), with a statistical significance level of $p < 0.05$. The analyses were performed using R software (v4.3.0).

**Results and discussion**

In terms of antioxidant activity, the hemolymph exhibited a consistent response across various treatments and over time. In contrast, the intervalvar fluid in the control group demonstrated a twofold increase in antioxidant activity between days 15 and 30, suggesting a potential accumulation of oxidative stress. Groups that were administered microalgae displayed stable or reduced levels. Furthermore, analysis of the microalgae utilized revealed significant differences in antioxidant activity within both the lysate fraction and the supernatant, indicating that each cocktail contributes uniquely to the redox profile and may differentially affect the response of oysters. Concerning immune parameters, antiprotease activity in the hemolymph remained stable, with no significant variations attributable to treatment or time. Conversely, the intervalvar fluid showed a treatment-dependent decrease, particularly in the group fed cocktail 2, where the reduction was progressive over time. Regarding lysozyme activity, hemolymph levels remained consistent on both sampling days for the control group and cocktail 1, with no significant differences observed. Only cocktail 2 exhibited a notable peak on day 15, followed by a decline on day 30. In the intervalvar fluid, the pattern was reversed: values were low and similar on day 15, but by day 30, an immune activation was evident, especially in the cocktail 1 group, with a significant increase; cocktail 2 and the control also increased, though without significant differences. Peroxidase activity in hemolymph showed an upward trend on day 30 across all groups, reaching statistical significance in the control and cocktail 2. In the intervalvar fluid, the response was more varied: the control group decreased significantly, while cocktail 2 exhibited a marked increase with significant differences. This study demonstrates that dietary microalgae from the Mar Menor lagoon can significantly modulate antioxidant activity and immune responses in oysters across different physiological compartments. The hemolymph showed relatively stable antioxidant activity, while the intervalvar fluid exhibited more dynamic responses. The microalgae cocktails, especially cocktail 2 induced distinct patterns of immune activation, notably in lysozyme and peroxidase activities. These findings suggest that carefully selected microalgae diets could potentially enhance the oysters' physiological resilience, which may be beneficial for bioremediation efforts in the Mar Menor ecosystem. However, the complex and sometimes contrasting responses observed between hemolymph and intervalvar fluid underscore the need for comprehensive evaluation of multiple parameters when assessing bivalve health and function in restoration contexts. Further research is warranted to optimize microalgae formulations and to investigate long-term effects on oyster populations and ecosystem services in the Mar Menor lagoon.

## Introduction

The growth of the global population, combined with shifts in dietary patterns, has elevated food security to a matter of critical importance. Within this context, seafood production has experienced significant growth over recent decades, exceeding 180 million tons in 2022 (FAO, 2024). The increase in production has also resulted in a higher volume of by-products, with fish by-products estimated to exceed 20 million tonnes (Yuan et al., 2024). Efforts to reduce the waste of these by-products have led to their use in the production of fishmeal and fish oil. Beyond their use in animal feed production, this biomass contains a significant range of bioactive compounds, offering opportunities to expand the potential applications of these by-products. Collagen falls into this category, with broad applications across food, cosmetic, and medical industries. Collagen serves as a key structural protein in animal tissues and it is particularly abundant in fish by-products, such as skin, scales, and bones. Conventional collagen extraction methods often suffer from inefficiencies, including long pretreatment and extraction times, low extraction yields and the reliance on enzymes (Laasri et al., 2023). Recent years, environmentally friendly techniques have been developed to significantly enhance extraction efficiency. Among these, ultrasound-assisted extraction (UAE) has emerged as a powerful approach, through cavitation, it can significantly improve collagen extraction times and yields. This study aimed to optimize the ultrasound-assisted extraction of collagen from the skin of *Pollachius virens*.

## Materials and methods

The skin of *P. virens* was minced and 10 g of tissue were mixed with 150 mL of 0.1 M NaOH to remove non-collagenous proteins. Two amplitudes (30% and 50%) of sonication were evaluated. Following sonication, the mixtures were incubated at 4 ºC for 24 hours. The soluble protein content in the supernatant was quantified, and the molecular weight distribution of the extracted proteins was analyzed by SDS-PAGE.

Collagen ultrasound-assisted extraction was then performed on 10 g of pretreated skins with 100 mL of 0.5 M acetic acid at 4 ºC. Both conventional acid extraction (AE) and ultrasound-assisted extraction at three amplitudes (40%A, 60%A and 80%A) were assessed. Re-extraction of collagen was also evaluated (80%A*2), the solid residue obtained after the initial extraction at 80% was subjected to a second extraction with 100 mL of fresh acetic acid solution under the same conditions for 10 minutes. The collagen yield was calculated based on hydroxyproline content in the extraction supernatant following the method described by Cissell et al. (2017). The molecular weight distribution of the extracted collagen was analyzed with SDS-PAGE.

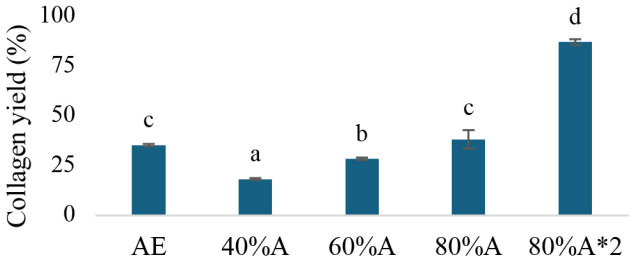

**Figure 1.** Extraction yield of collagen performed with conventional extraction for 48 hours (AE) and ultrasound-assisted extraction (40-80%A and 80%A*2). Different letters indicate significant differences ($P<0.05$).

*(Continued on next page)*

**Results and discussion**

A positive correlation was observed between the amplitude of sonication and the yield of protein extraction during both the pretreatment and collagen extraction stages. During the alkaline pretreatment, sonication at 50% amplitude for 20 minutes achieved a protein yield of 7.7 g per 100 g of dry skin. Notably, extending the treatment by maceration for an additional 24 hours did not further increase the protein concentration, unlike other amplitude and time combinations evaluated.

The molecular weight profile of the proteins extracted indicated that collagen was not co-extracted during this step, suggesting that it remained intact. This approach significantly accelerates the removal of non-collagenous proteins, reducing the required processing time from 6–24 hours to merely 20 minutes without compromising the structural integrity of the collagen present in the skin.

For the subsequent collagen extraction, the effects of varying amplitude were systematically assessed (Figure 1).

Collagen extraction using ultrasound at 80% amplitude for 20 minutes resulted in a collagen recovery of 38.3%, comparable to the 35.4% obtained through conventional method after 48 hours of extraction. Re-extraction of the solid residue from the initial extraction further increased total final yield to 87.3%, the highest among all tested conditions. Similar results were obtained for baltic cod (*Gadus morhua*) skin after 24 hours of extraction (Sadowska et al., 2003). The molecular weight distribution of the extracted collagen revealed the presence of protein bands corresponding to the α, β, and γ chains characteristic of type I collagen (Shoulders and Raines, 2009).

This methodology offers a efficient route for the valorization of by-products from the aquaculture and fisheries industries, enabling collagen recovery through an extraction process that can be completed in approximately one hour.

**Introduction**

The growing demand for sustainable and environmentally friendly health solutions in aquaculture has intensified interest in natural bioactive compounds. Screening plant extracts from aromatic and traditional medicinal herbs offers promising opportunities for developing therapeutic agents aligned with ecological and economic sustainability. The Cistus genus, a Mediterranean shrub, is known for its high polyphenol content and secondary metabolites with potential antiviral properties (Zalegh et al. 2021).

Viral infections remain a major challenge in aquaculture, causing significant economic losses and threatening the long-term viability of the industry worldwide. While preventive measures such as vaccines are available for certain pathogens, effective antiviral treatments are still limited. In this context, natural compounds provide a valuable source of new bioactive molecules, many of which remain unexplored. Investigating their biological activity is essential to identify novel mechanisms of action and alternative therapeutic strategies (Khang et al. 2025).

This study evaluates the antiviral activity of an aqueous extract from a Mediterranean plant against a panel of viruses that are highly relevant to the aquaculture sector. By exploring the pharmacological potential of this extract, this study contributes to the valorisation of forest waste from *Cistus* species. integrating circular economy principles into sustainable aquaculture practices.

**Materials and methods**

An aqueous extract was prepared from dried plant material, which was then solubilized in dimethyl sulfoxide for testing. The antiviral activity was then assessed *in vitro* against five relevant fish viruses: spring viremia of carp virus (SVCV), viral hemorrhagic septicemia virus (VHSV), cyprinid herpesvirus 3 (CyHV-3), tilapia lake virus (TiLV), and common carp paramyxovirus (CCPV).

Each virus was incubated with host cells at virus-specific multiplicities of infection (MOIs) for two hours at the optimal infection temperature. To evaluate the antiviral activity, three experimental conditions were evauated: (i) pre-incubation of viral particles with the extract, (ii) pre-treatment of cells prior to infection and, (iii) post-infection treatment to asses effects on later replication stages. Antiviral efficacy was evaluated by quantifying the percentage of infection inhibition compared to untreated controls.

| Virus | Primary host species(es) | $IC_{50}$ (µg/ml) |
|---|---|---|
| Spring viremia of carp virus (SVCV) | Cyprinids | 33 |
| Viral hemorrhagic septicemia virus (VHSV) | Salmonids | <12 |
| Cyprinid herpesvirus 3 (CyHV-3) | Cyprinids | <12 |
| Tilapia lake virus (TiLV) | Tilapias | 12 |
| Common carp paramyxovirus (CCPV) | Cyprinids | <12 |

*(Continued on next page)*

**Results**

The aqueous extract exhibited potent antiviral activity against all of the viruses tested. Preliminary inhibitory effects were observed with VHSV, CyHV-3, TiLV and CCPV, while more robust inhibition was demonstrated for SVCV. Extended experiments with SVCV provided further insights into potential mechanisms of action. The half-maximal inhibitory concentration ($IC_{50}$) values for each virus are summarized in the table below:

**Discussion**

The aqueous extract demonstrated antiviral activity against all the fish viruses tested, although the extent and depth of the analysis varied depending on the viral model. Antiviral effects were observed when cells were treated throughout the full infection cycle for VHSV, CyHV-3, TiLV, and CCPV, suggesting that the extract can interfere with one or more stages of the viruses replication. However, further studies are needed to clarify these mechanisms.

A broader experimental design for SVCV revealed that antiviral activity was primarily observed when the extract was applied during early infection stages, either by direct interaction with viral particles or by pre-treatment of cells. No inhibitory effect was detected when the extract was added post-infection, indicating it does not affect later stages of viral replication. These results suggest that the extract acts on viral attachment, entry, or modulation of host cell susceptibility (Aoki-Utsubo et al. 2018)

Overall, these findings demonstrate the extract's multi-target antiviral potential and support the integration of botanical compounds into sustainable fish health management strategies.

**Conclusion:**

This study highlights the antiviral potential of a plant-derived aqueous extract against multiple fish viruses. The extract was particularly effective during the early stages of infection, suggesting its suitability as a preventive strategy in aquaculture. Its use aligns with circular economy principles by valorizing botanical resources for sustainable, low-impact health solutions. Further research will be essential to isolate the active compounds and support the translation of these findings into practical applications in fish farming systems.

**Introduction**

The study and identification of pathologies in marine species are essential for health management in aquaculture, as well as for the knowledge and conservation of marine biodiversity and promoting scientific dissemination. However, the study of this area has been limited by the need to use real biological specimens, often requiring dissection or sacrifice, which poses significant ethical, logistical, and pedagogical drawbacks. In recent years, advances in three-dimensional modelling technologies have improved the way in which knowledge is transmitted. Despite its great potential, the application of 3D modelling in the field of marine pathology remains scarce and underdeveloped in educational contexts. This highlights the need to explore and validate new visual and digital approaches that allow replacing the use of real organisms, in line with the "3Rs" principle (Reduce, Reuse and Recycle), while also improving the accessibility, understanding and dissemination of these contents.

This work arises from the desire to respond to these limitations by developing high-precision digital models that allow observing and understanding the external pathologies in sea bream. This approach is intended to contribute to the advancement of more ethical and technologically modern teaching, as well as offering a support resource for the training of future professionals in marine sciences, veterinary, and marine conservation.

**Materials and methods**

The software used for modelling was ZBrush, developed by Pixologic and currently managed by MAXON. ZBrush is a 3D modelling environment specialized in digital sculpture, which allows working with high-resolution organic models thanks to a proprietary architecture called "pixol". Pixol stores additional three-dimensional information such as depth, orientation and colour of each point on the surface. First step: the cone base is obtained, a fusiform structure with the exact dimensions of the reference model but without any type of detail (Fig.1); second step: modular body creation (eyes, mouth, operculum, fins…) (Fig. 2); third step: projection of the three-dimensional surface of the model onto a two-dimensional plane; fourth step: to represent alterations, pathologies, infections in the model.

**Results**

This methodology enables a highly realistic visual finish, resulting in an accurate base model that accurately represents the fish species (Fig. 3A). The model developed illustrate some of the typical pathologies of bream: lordosis (Fig. 3B), as an example of skeletal alterations; infection by *Tenacibaculum maritimum* (Fig. 3C), as an example of an identifiable skin infection; and the ulcerative process known as "red rash" (Fig. 3D)., a multifactorial pathology typically associated with intensive aquaculture.

To ensure the model utility, a website has been created where all of them can be viewed. The website uses the Sketchfab, an online platform that showed 3D models to be viewed interactively without requiring additional software. This results in a simple but organized web page that allows users to conveniently visualize and explore the generated models.

**Conclusions**

The developed models have a high level of anatomical precision and detail that allows them to be used in the educational and outreach sectors. They serve as visual tools for aquaculture technicians or veterinary, and students of marine biology, aquaculture, veterinary or environmental sciences, facilitating the understanding of the morphology and common diseases of this species of commercial interest. This work highlights the importance of combining scientific knowledge, technology and aesthetic sensitivity to create innovative resources that promote an education that is more respectful of living beings and more accessible to everyone.

## Introduction

The aquaculture sector increasingly prioritises resource efficiency and sustainability, particularly within recirculating aquaculture systems (RAS), which can play a pivotal role in mitigating environmental impact by facilitating water reuse and reducing waste accumulation. Optimising feed formulations in RAS is essential for enhancing nutrient efficiency, with macroalgae by-products, including those obtained from agar extraction industries, representing a sustainable alternative that does not compete with terrestrial resources [1]. However, these by-products' high non-starch polysaccharide (NSP) content may hinder digestibility in carnivorous fish species, limiting their dietary inclusion. To address this challenge, nutritional strategies such as pre-treatments (e.g., chemical hydrolysis) and exogenous enzymes have been proposed to improve NSP breakdown and enhance nutrient bioavailability [2]. Despite this drawback, NSP-rich ingredients may improve RAS performance by enhancing faecal binding, resulting in larger and more compact faeces that are efficiently removed by mechanical filtration [3], ultimately lowering management costs. Thus, this study explores the potential of high inclusion of an alkaline pre-treated *Gelidium corneum* solid by-product (GBP) obtained from the agar extraction industry, both alone and in combination with exogenous enzymes, on digestibility and fish faecal physical properties, aimed at tailoring RAS aquafeed for European seabass.

## Materials and methods

Four isonitrogenous, isolipidic, and isofibrous experimental diets (CP 44%, EE 16%, crude fibre 1.7%) were formulated: one control diet and three test diets with 15% alkaline pre-treated *Gelidium corneum* by-product (GBP; NaOH 1N, 15 min autoclaving), replacing soybean and whole wheat meals, supplemented or not with 1% or 2% of a commercial thermostable NSP-degrading enzyme complex (Natugrain® TS-Feed Enzyme, BASF, Germany). All diets included 0.5% DM chromic oxide as a digestibility marker. The trial was conducted at CIIMAR (Matosinhos, Portugal) using 108 European seabass (79.9±2.4 g) randomly distributed into 12 thermo-regulated RAS tanks equipped with faecal sedimentation columns. Diets were randomly assigned to triplicate groups, fish were hand-fed to satiation twice daily, and faeces were collected before the first meal, centrifuged, and stored frozen per tank over 14 days. Tanks were cleaned 30 minutes post-feeding to remove residual waste. Apparent digestibility coefficients (ADCs) for dry matter, protein, lipid, gross energy, inorganic and organic acid detergent fibre (ADF), neutral detergent fibre (NDF), and amino acids were determined following standard protocols [4]. Fresh faecal samples from each tank were analysed for particle size distribution (fines ≤0.5 mm; medium 0.6–1.2 mm; large ≥1.2 mm) using volumetric and photometric methods [5]. Data related to ADCs and faecal physical traits were analysed by ANOVA using the PROC GLM of SAS, with diet as a fixed effect. Least square means were compared using Bonferroni's test, with a significance level set at $p<0.05$.

## Results and discussion

The ADCs of energy (84.4%, on average), dry matter (67.6%), protein (92.6%), and lipid (97.5%) were similar among control and the three test diets ($p>0.05$), aligning with reference values reported for most carnivorous fish species [6]. Inorganic and organic ADF fractions were undigestible in all dietary treatments. In contrast, the digestibility of the NDF fraction was higher in the GBP diet supplemented with 2% Natugrain® compared to the control and non-supplemented or 1% Natugrain® supplemented GBP diets (35.5% vs. 21.8% on average, $p<0.05$). These results confirm the reported beneficial effect of dietary supplementation with exoenzymes (i.e., carbohydrases) to complex polysaccharides, releasing carbohydrate oligomers and

*(Continued on next page)*

monomers, which reduces polymerisation and viscosity and increases bioavailability to the animal [7]. The ADCs of essential amino acids remained high across all diets, with those of lysine and methionine, key for growth and metabolism, exceeding 90%, indicating that 15% GBP inclusion did not affect their bioavailability. In addition, dietary inclusion of GBP, alone or enzyme-supplemented, enhanced the physical properties of faeces, increasing the volume (+12%) and length (+13%) of large-sized faeces (≥1.2 mm) compared to the control diet ($p<0.05$). This effect is likely attributed to fibre components of GBP, which may enhance water retention and contribute to a more compact faecal matrix, increasing gastrointestinal motility and promoting faecal aggregation [5].

**Conclusions**

Overall, 15% dietary inclusion of GBP did not affect energy, macronutrients, and amino acids digestibility, whereas supplementing the GBP-based diets with 2% of a carbohydrase enzyme complex enhanced the NDF digestibility. In addition, diets containing GBP improved faecal characteristics. Given the importance of water quality management in RAS, these findings suggest that incorporating low-cost by-products, such as GBP, into aquafeeds may optimise waste management and increase the economic sustainability of closed systems. Further studies should assess the impact of dietary GBP inclusion on fish growth, health, and water quality, while optimising aquafeed formulations for different farming conditions to enhance resource efficiency.

# PUBERMULLET PROJECT - UNRAVELLING THE PUBERTAL SIGNALS AND GAMETOGENESIS DEVELOPMENT IN FARMED FLATHEAD GREY MULLET (*Mugil cephalus*)

E. Fatsini*[1], A. Roque[1], S. Salcedo-Martínez[1], N. Duncan[1]

[1]Institute of Agrifood Research and Technology (IRTA), Sant Carles de la Ràpita, Crta. Del Poble Nou Km 5.5, 43540 Sant Carles de la Rápita, Tarragona, Spain

E-mail: elvira.fatsini@irta.cat

**Introduction**

The flathead grey mullet (*Mugil cephalus*) is the most commercially valuable mullet species and one of the top omnivorous marine fish in global trade. With a trophic level of 2.5, it aligns closely with molluscs and is well-suited for aquaculture due to its resilience and adaptability to various farming conditions. In 2019, global production reached 118,000 tons, with aquaculture accounting for just 6,124 tons, relying entirely on wild-caught juveniles[1]. This species is economically prized, particularly for its salted and dried roe, "*bottarga*", considered a delicacy in the Mediterranean and Asia. However, wild stocks are declining, and aquaculture is unsustainable due to the species' inability to reproduce in captivity. Flathead grey mullet do not mature or spawn in intensive culture. Research at IRTA-La Ràpita has made progress using recombinant gonadotropins (rGth) to stimulate spermatogenesis and oogenesis[2,3], but key aspects of the species' reproductive biology remain unknown. Moreover, numerous significant questions regarding the reproductive biology of the flathead grey mullet remain unanswered, and discovering their solutions will be crucial in achieving a closed cycle within aquaculture conditions. Some of these questions are: i) What are the puberty signals of the farmed flathead grey mullet? ii) What are the underlying patterns of gametogenesis prior to, during and after puberty in the flathead grey mullet? The PUBERMULLET project aims to address questions about puberty signals and gametogenesis patterns to close the life cycle in captivity. The ultimate goal is to support sustainable aquaculture of this species with minimal reliance on fish oil and fish meal.

**Material and Methods**

For this purpose, three experimental WPs will be performed in this project:

*WP1. Identification of the physiological and molecular signals when the gonad is receptive to rGths to induce puberty in the farmed flathead grey mullet juveniles.*

This WP aims to describe the putative signals in the BPG axis at different levels in the juvenile stage to reveal the onset of puberty. Steroids (E2, 11-KT and T) concentrations will be determined in blood plasma using specific antibodies by ELISA (T1.1). Brain and gonad transcriptomic profiles focusing on genes related to puberty (e.g. *kiss1r*, *gnrh2*, *gnrh3*, *leptin*, *amh*, *igf3*), gonadotropins (*fshr* and *lhr*) and their variation according to different juvenile stages will be quantified using qPCR. Histology of the gonads will be performed to observe the different evolution of the gonads, and *in situ* hybridisation will be carried out to observe the localisation of some specific genes in males and females (*fshr* and *lhr*) (T1.2). At the end of this WP, it is expected to understand the relationship between reproductive physiological responses (biochemical and molecular levels) associated with the onset of puberty.

*WP2. Determine the miRNAs biomarkers associated with when the gonad is receptive to recombinant gonadotropins to induce puberty in the farmed flathead grey mullet.*

Recently, several studies have demonstrated the modulation of the miRNA's profiles during the different life stages in several fish species. This innovative approach would lead to finding a post-transcriptional biomarker associated with early maturational development in the farmed flathead grey mullet. For this purpose, blood plasma from the different life stages (juvenile, pubertal and breeders) will be collected. A small RNA-seq next-generation sequencing (NGS) will be run to produce circulating miRNA profiles of blood plasma and to determine the differences among life stages (T2.1). Preparation of small RNA libraries, sequencing on the NextSeq Illumina platform and bioinformatics analyses of the data will be carried during a secondment performed in the Institute of Marine Sciences (ICM-CSIC) in Barcelona (Spain) (T2.2). It is expected to observe putative differences among these groups of animals and to identify possible useful miRNA biomarkers for the onset of puberty and maturation of the farmed flathead grey mullet.

*(Continued on next page)*

*WP3. Characterisation of the effect of rGths on the early stages of maturational development in the flathead grey mullet.*
Once a stage of gonadal development that may be receptive to rGths has been defined (physiological, molecular, and epigenetic) in the farmed flathead grey mullet from the previous WPs, a deep study in gametogenesis and quality will be performed in these early breeders. For this purpose, the same group of fish established in the WP1 will be monitored through the early stages of gonadal maturation, and some fish will be sacrificed to perform *in vitro* studies and some will be induced to carry out *in vivo* trials to examine the receptiveness of the gonad to the rGths. For the *in vitro* experiments, individuals will be sacrificed, explants of testis and ovaries will be performed using different rGth concentrations and growth factors to observe the evolution *in vitro*. Periodically, samples will be collected to perform histology, enzymatic activity and molecular analysis. The antioxidant capacity will be determined by the enzymatic activity using protocols adapted for the mullet. Moreover, apoptosis evaluation will be performed by studying the expression by qPCR of anti-apoptotic (*bcl-2*, *bcl-x*, *mcl-1*) and pro-apoptotic genes (*bad*, *bax*, *bak*, *bok*) in the gonads (T3.1). Medium from the cell culture will be collected, and sex steroids will be measured. To observe this evolution *in vivo*, individuals will be initially induced with different doses of rFsh, and early stages of gametogenesis and blood will be extracted to observe the evolution in plasma sex steroids of the animals induced with the different doses (T3.2). It is expected to understand the process of gametogenesis in the farmed flathead grey mullet using this multidisciplinary approach, covering several aspects of the development and germ cell quality.

**Expected results**
This project will provide crucial information about the different signals of the onset of puberty in a promising species for future aquaculture diversification in Europe, flathead grey mullet. Secondly, it will provide the development of gametogenesis at different levels of the BPG axis, which will have a positive impact in mullet and other species production.

## Introduction

Aquaculture is vital for global food security, especially in developing regions where fish is a key protein source. The sector's rapid growth supports millions of livelihoods but is vulnerable to disease outbreaks that threaten aquatic health, ecological safety, and sustainability. Overuse of antibiotics to control diseases raises concerns about antimicrobial resistance and drug residues in the food chain. While ecological aquaculture offers solutions, scaling it without losing productivity is difficult, making innovative, sustainable disease management essential. The COST Action BioAqua tackles this by creating child-friendly educational materials on fish welfare and One Health to inspire future generations toward sustainable aquaculture.

## Material and Methods

The BioAqua comic designed science communication, entitled "Fish Superpowers!", has been crafted to disseminate the state-of-the-art technologies used for sustainable aquaculture to young children at school (non-specialist audiences). It features several chapters explaining the main topics related to aquaculture, food safety, and sustainability. The protagonists of the comic are the three fish heroes in vibrant colours [1], comic style—Finley, Bubbles, and Stella—with George the Farmer and Dr. Clara, the veterinarian. The BioAqua comic introduces complex concepts, *viz*., risk assessment, antibiotic alternatives, and the One Health approach [2] in a straightforward, relatable narrative, through the story of three lively fish and their vet, Dr Clara [3]. As teaching science and literacy together can be challenging, the comic uses fictional characters and stories as tools to spark curiosity and promote equal learning opportunities. This approach follows the principles of Universal Design for Learning and supports lifelong development of pedagogical skills [3]. The colour combinations of green–red, green–brown, blue–purple, green–blue, light green–yellow, blue–grey, green–grey, and green–black were avoided, keeping in mind the individuals with colour-blindness (protanopia, deuteranopia, and tritanopia). High contrast was used in hue, saturation, and brightness; textures or patterns were added to visuals. The comic uses the Open Dyslexic font to make reading easier for children with dyslexia. However, studies suggest it may not always lead to a significant improvement in reading speed or accuracy.[4]. Storytelling choices were driven by the need to balance emotion and interactivity [5]: Finley reflects the readers' curiosity [6], Bubbles expresses caution (mirroring natural scepticism), and Stella represents excitement and optimism. These emotional anchors allow children to connect with the story through different entry points [5]. If a storyteller teaches children, they are encouraged to ask "guess what happens next" at the end of each chapter, enabling prediction and critical thinking [3].

*(Continued on next page)*

## Results

The comic provides multiple educational sources: Science education (fun introduction to microbiology, nutrition, and environmental science), Health education (lessons on why food safety and hygiene matter), Civic and ecological education (understanding sustainability, shared responsibility, and the One Health concept). The comic presents six chapters: Chapter 1: The Mystery of the Tired Fins: Our fish heroes start feeling sluggish and confused, prompting a visit from Dr. Clara to find out what is wrong. →This opening chapter introduces the idea that good nutrition is central to keeping fish healthy and thriving. Chapter 2: A Visit from Dr. Clara: Dr. Clara introduces a new "super feed", enriched with safe biomolecular ingredients → Reflects innovation in fish nutrition and science communication. Chapter 3: Testing the Super Feed: The fish eat the feed and experience positive effects: more energy, shinier scales, clearer thinking → Demonstrates measurable benefits of safe, bio-based interventions. Chapter 4: One Health: The fish discover that keeping them healthy also protects the people who eat them and the water they live in → Highlights BioAqua's integrative approach to health. Chapter 5: Aquaculture Matters: George explains aquaculture's role in global food production. The fish feel proud of their role → Encourages understanding of aquaculture as a sustainable food system. Chapter 6: A Cleaner Future: The fish reflect on the importance of sustainable farming practices and clean water → Emphasises eco-friendly aquaculture aligned with EU Green Deal goals.

The link to download the comic is the following: http://hdl.handle.net/10197/28717.

## Conclusions

This educational comic communication serves to promote awareness about aquaculture and essential aspects associated with this critical practice by combining humour, an emotional approach, as well as vibrant visuals. The comic highlights the importance of nutritious, safe feed in maintaining fish health and environmental protection. It encourages young readers to see the connections between personal choices, animal well-being, and global sustainability in a fun and accessible manner. Moreover, the use of relatable characters and storytelling helps demystify complex scientific concepts, making them more approachable and memorable for children. The inclusive design considerations, such as colour-blind friendly palettes and dyslexia-supportive fonts, demonstrate a commitment to accessibility, ensuring the material can reach diverse learners with varying needs.

# RELEVANCE OF BARLEY PROTEIN CONCENTRATE FOR FEEDING OF AFRICAN CATFISH JUVENILES: GROWTH PERFORMANCE AND BIOCHEMICAL PARAMETERS

Gy. Fazekas[1], Sh. Kumar[2], M. Dubey[2], A. Szűcs[1], K. Bogár[1], L. Ardó[1], V. Banjac[3], A. Terhes[1], Zs. J. Sándor [1*]

**Introduction**

More than 95% of soymeal, a popular component of animal feed, is imported. Due to restrained soybean production in Europe, as consequence, the fish feed production needs new sources of protein to satisfy their requirements. The protein concentrates have the advantage over whole meals as the non-digestible fibre is eliminated which allow for the possible use of higher levels of plant material in fish diets. Barley protein concentrate (BPC), as a new alternative ingredient in aquaculture, has rarely been tested in fish. By production up to 150 million tons, barley is among the top four produced grains worldwide. The specific composition can vary depending on the processing method and the purity of the concentrate. In the factory of Pannonia Bio Ltd. at Dunaföldvár, Hungary the annual production reached 45 thousand tons. In the frame of AQUAEXCEL TNA project, we aimed to determine the optimum inclusion level of BPC as novel plant protein source, and to assess the best soybean supplementation ratio in the diet of African catfish.

**Materials and methods**

Five isonitrogenous (450 g/kg) and isolipidic (110 g/kg) diets were formulated for African catfish juveniles (*Clarias gariepinus* × *Heterobranchus longifilis*). The control diet (CTR) contained similar ingredients as are used in commercial fish diets, in the other four experimental treatments soybean flour and SPC was replaced by barley protein concentrate in 25-50-75-100%. According to this the BPC content of the diets was 5-10-15-20% (Table 1.). All diets were supplemented with fish premix to ensure the limiting micronutrients and amino acids. The feeding trials involving 1500 juvenile fish (average body weight of 36.5 ± 0.6 g) lasted ten weeks, each replicated three times (90 fish per tank) and reared in a recirculation aquaculture system equipped with 1 $m^3$ fiberglass tanks. During the trials, the fish were fed at a 3% feeding rate using automatic feeders. Water quality parameters (temperature, dissolved oxygen, and pH) were monitored regularly, while nutrients (ammonia, nitrites, and nitrates) were monitored on a weekly basis. At the end of trial samples for digestive enzymes activity, blood chemistry, ALT and AST activity in the liver, and for gene expression related to the growth and metabolism were taken parallel with growth performance and nutrient utilization indicators.

**Results and Discussion**

After the 10-weeks of feeding statistical differences in terms of growth performance and nutrient protein utilization were observed between treatments. The trial with graded BPC levels (replacing 25–100% of soybean meal) showed no growth reduction at 5–10% BPC inclusion, but at higher levels (15–20% BPC) growth performance declined sharply. Weight gain dropped from 212.8g in control to 156.5g and 111.0g at BPC15 and BPC20, respectively and SGR fell from ~2.9%/day to 2.6 and 2.2%/day at the highest inclusion. FCR remained low (~0.69–0.85) in diets up to treatment BPC15, but jumped to 1.44 in the BPC20 group, indicating poor feed utilization at that extreme inclusion. PER showed a similar pattern: it held steady (~2.8–3.2) in control and 5–15% BPC diets but dropped to 1.65 in the BPC20 group. The CONTR and BPC5 groups exhibited similar growth performance throughout the period, while treatments BPC20 and BPC15 showed a noticeable decline after 28 days of feeding, which became more pronounced at the 49-day sampling time compared to CONTR and BPC5.

*(Continued on next page)*

Generally moderate inclusion of alternative proteins in fish diets tends not to drastically disturb basic blood parameters, provided nutritional requirements are met. There were fluctuations in several parameters, such as glucose and total protein but these did not indicate any pathological condition. Various other blood parameters (e.g., urea, creatinine, minerals) generally stay within normal ranges on alternative diets unless the fish are experiencing toxicity or severe metabolic disturbance. The ratio of blood urea nitrogen to creatinine was significantly altered at 20% BPC (8.0 vs ~2.4–4.6 in other groups) which might indicate a subtle shift in protein metabolism at that extreme diet (higher relative blood urea nitrogen suggests more protein catabolism or reduced growth using that protein. Similarly, plasma total cholesterol was affected by diet tended to rise with 10–20% BPC inclusion (132.6 mg/dL at BPC20 vs 116 mg/dL in CONTR) comparable with study on African catfish fed with mealworm containing diet (Gebremichael et al, 2023). Despite these changes, cholesterol values remained in a moderate range, and other liver function indicators (like bilirubin or bile acids) were normal, suggesting no severe liver impairment. In Atlantic salmon, inclusion of barley protein caused no reported abnormalities in blood metabolites – consistent with the lack of antinutritional factors in BPC (Bell et al, 2016). In conclusion, based on growth and nutrient utilization parameters, as well as blood biochemical analyses, it can be said that feeding BPC to tested young animals is recommended at a maximum of 10% content.

# EFFECT OF HIGH SEA WATER REARING TEMPERATURE ON THE ONSET OF EARLY PUBERTY IN MALE AND FEMALE EUROPEAN SEA BASS

S. Sarih, C. Zapater, A. Gómez and A. Felip*

Fish Reproductive Physiology Group
Department of Fish Physiology and Biotechnology
Instituto de Acuicultura Torre de la Sal (IATS)
Consejo Superior de Investigaciones Científicas (CSIC)

E-mail: afelip@iats.csic.es

## Introduction

Climate change is a serious concern for the aquatic environment, as it alters the physical and chemical properties of seawater causing negative impacts on fish. Among its many effects, the increase of atmospheric greenhouse gases has led to a rise in average sea surface temperatures. Fish are poikilothermic and are therefore extremely sensitive to changes in environmental temperature. Exposure of adult fish to warm temperatures is known to impair reproduction, although the long-term reproductive impact during early life stages remain poorly understood. The European sea bass (*Dicentrarchus labrax* L.) is a marine species of high commercial value, in which a significant proportion of individuals exhibit precocious puberty during the grow-out phase, when they are reared to marketable size. A situation that aquaculture producers want to prevent. The goal of this study was to evaluate the effect of high sea water rearing temperature on the onset of early puberty in this species. Growth and gonad maturation in juvenile 1-year-old male and 2-year-old female European sea bass were analysed, and its consequences in productive terms were considered.

## Materials and methods

Juvenile sea bass (initial body weight (BW) of 14.0 ± 4.1 g) were provided by Piscialba-Piscifactorías Albadalejo S.L. (Murcia, Spain). Eight-month-old fish were sized and weighed, and the smallest 85% of the animals were considered potentially male fish (n = 510 fish) whereas the largest 15% were considered potentially female fish (n = 90). Potential male fish were distributed in six 500-l circular fiberglass tanks (n=85 fish/tank) whereas potential female fish were distributed in two 500-l circular fiberglass tanks (n = 45 fish/tank). After an acclimatization period of 30 days, two experimental groups for each sex were organized in triplicate in males and duplicate in females: control group (CG) that was maintained under natural seawater temperature conditions at the IATS facilities (40°08′15″ N; 0°10′12″ E) and high-temperature group (HTG) that was maintained at a temperature that was 3-4 ºC above that of the CG. The survival rate as well as BW and fork length (FL) of fish was periodically measured. Blood samples were collected, and the plasma was stored at -20ºC until hormonal analysis. In the case of males, in order to assess the testicular growth and the proportion of early maturing fish, 4-10 animals per group were sacrificed from July to February during their first year of life. The ovarian growth and the incidence of early onset puberty was assessed in 4-10 females per group that were sacrificed from October to February during their second year of life. Gonad was removed and weighed to determine the gonadosomatic index (GSI) and small pieces of tissue were fixed for histological analysis and assessment of the stages of testicular and ovarian development. The percentage of early maturing males was also evaluated from November to onwards by applying gentle hand pressure to the abdomen of all fish. Circulating plasma levels of follicle stimulating-hormone (Fsh) and its content in the pituitary were evaluated in both sexes. Plasma levels of testosterone (T), 11-ketotestosterone (11-KT) and estradiol ($E_2$) were also analysed in males, whereas levels of $E_2$ and vitellogenin (Vtg) were analysed in females.

*(Continued on next page)*

## Results

After five months of experiment, male sea bass reared at a high temperature (HTG) showed a lower survival rate than that of the CG (66% and 96%, respectively). Males in HTG was approximately 12.61 % lower in weight and 3.14 % smaller in length than that of CG at 17 months of age. The condition factor varied between 1.01 and 1.81 in fish at HTG, while it was around 1.02-2.14 in the CG. First significant increase of the GSI was observed after 4 months of experiment in fish of the CG (GSI= 0.47 ± 0.42%) compared to males reared in HTG (GSI= 0.05 ± 0.03%). In February, during the tentative testicular growth period, GSI of the HTG was 1.66 ± 0.33% whereas values in the CG were significantly higher (2.74 ± 0.26%). The histological analysis of testis revealed clear differences between CG and HTG, where the percentages of gonadal stage III (mid recrudescence) in the CG reached 17% in October and 57% in November whereas the HTG group displayed 14.3% in December. In February, the percentages of gonadal stage IV (late recrudescence) in the CG was 89% and 11% in stage V (full spermiating testis) where all males in the HTG reached gonadal stage IV. Furthermore, the proportion of precociously spermiating males was higher in the CG than that of HTG from December to March, with a peak of 78% in the CG in comparison to 23% in the HTG in February. Of note, spermiation time lasted one month longer, until April, in the CG. Also, males in the HTG exhibited an increase of plasma and pituitary content of Fsh, whereas the levels of T and 11-KT remained unchanged in both experimental groups. In the case of females, no significant differences in growth performance were observed between CG and HTG. The condition factor ranged from 1.19 and 1.77 in the HTG and from 1.18-1.61 in the CG group. Although values of GSI were higher in the CG compared to those of HTG, no significant differences were observed. In February, values of GSI of the HTG were 3.65 ± 1.04% whereas those of the CG reached 6.58 ± 0.84%. Histological analysis of ovaries revealed that the incidence of early onset puberty in females was similar in both groups. Accordingly, all females in the CG and HTG showed oocytes in late vitellogenesis in February, although the animals in the HTG group entered vitellogenesis one month later than those in the GC group. Finally, females in both experimental groups exhibited similar Fsh and $E_2$ plasma levels, whereas the levels of vitellogenin increase later in the HTG group, aligning with the delayed vitellogenesis observed histologically.

## Discussion

These findings show that high sea water rearing temperatures reduce the long-term growth performance of juvenile male European sea bass during their first year of life. Although males can start spermatogenesis, fish in the HTG show a delay in the progression towards advanced testicular stages and a reduction in the time fish remain in spermiation. On the other hand, high sea water rearing temperatures do not affect growth performance of female sea bass during their first two years of life and the incidence of early puberty is similar in both CG and HTG groups. Accordingly, high sea water rearing temperatures affect the reproductive axis of European sea bass at multiple levels, although the occurrence of early sexual maturation persists and, in turn, its side effects need to be avoided in terms of production. Finally, high sea water rearing temperatures can impact spawning season, sometimes shortening it, thus influencing the life history traits of fish species and populations.

## Introduction

The European sea bass (*Dicentrarchus labrax* L.) is one of the most important marine fish species consumed in Europe, primarily due to its affordable market price, appealing aroma, and desirable flesh quality. Several studies have highlighted differences in the chemical composition between wild and farmed sea bass. Moreover, deterioration in fillet texture during sexual maturation is a well-documented concern in aquaculture species, posing a challenge to the industry when marketing fish for consumption. It has also been suggested that certain flesh quality traits in farmed fish may be influenced by lifestyle or the sheltered conditions characteristic of aquaculture systems. In the specific context of sexual maturation, the accepted, but scarcely proven paradigm is that this biological process reduces meat quality by altering fatty acid composition—particularly due to the mobilization of polyunsaturated fatty acids (PUFAs) to meet the gonadal requirements. Early sexual maturation in European sea bass is known to negatively impact growth, resulting in size variation and reduced overall biomass. However, there is a lack of data regarding the direct effects of sexual maturation on muscle lipid content, and especially on fatty acid composition. Accordingly, the aim of this study was to evaluate the effects of early sexual maturation in immature and maturing male and female sea bass, using the muscle fatty acid profile as an indicator of fillet quality in this species.

## Materials and methods

Fish were sampled in February, coinciding with the reproductive season of *Dicentrarchus labrax*. A total of 57 individual muscle samples (4 cm × 2 cm) were collected from the anterior left dorsal muscle and stored at −80 °C until analysis. Total lipids were extracted from freeze-dried tissue using the method of Folch et al. (1957), then transmethylated and analyzed by gas chromatography (Guinot et al., 2013). The sexual status of each fish was determined histologically, based on the developmental stage of the testes or ovaries. Specifically, 17 immature and 12 maturing one-year-old males were classified, along with 12 maturing two-year-old males. Among females, 8 immature and 3 maturing two-year-old fish were identified, as well as 5 maturing three-year-old individuals. Fatty acid profiles were analyzed using Principal Component Analysis (PCA), which was applied to highlight segregation among the different experimental groups—specifically according to sex, age, and degree of sexual maturity.

## Results

Muscle lipid content and fatty acid composition in immature and maturing (precocious) one-year-old male European sea bass showed no significant changes. However, regardless of reproductive stage, significant differences in fatty acid composition were observed between one- and two-year-old males. Similarly, no significant changes were detected in the muscle lipid content or fatty acid composition of immature and maturing two-year-old females. In contrast, two-year-old females exhibited marked differences in fatty acid composition when compared to three-year-old females. Overall, the findings of this study did not indicate a drastic change in the flesh fatty acid profiles associated with sexual maturation, as the observed differences were not linked to reproductive status or sex. Instead, the results suggest a cumulative dietary effect on the muscle fatty acid profile, contributing to the age-related differences in fatty acid composition observed among the fish.

## Discussion

This study provides novel insights into the fatty acid composition associated with sexual maturation in European sea bass. The findings show no significant differences in muscle lipid content or fatty acid composition between immature and maturing individuals of the same age, nor between males and females. While age-related differences in fatty acid profiles were observed, these were not linked to reproductive status. This suggests that early sexual maturation does not markedly affect fillet quality in this species, and thus, the associated economic impact on aquaculture may be less substantial than previously assumed.

**Introduction**

The sustainable intensification of aquaculture production is fundamentally dependent on the capacity of cultivated fish to adeptly manage a range of environmental and physiological stressors and challenges. Preserving optimal health and resilience in aquatic organisms is of utmost importance for productivity, welfare, and the sustainability of the sector. In this regard, the development of functional feeds constitutes a promising and ecologically sound strategy aimed at enhancing fish health and fortifying their innate defense mechanisms. Algae are gaining prominence in this field, as they provide an abundant source of bioactive compounds with considerable potential as functional ingredients. Considering the pivotal role of the gut mucosa in fish health and homeostasis, a positive interaction of algae-derived ingredients with the fish's intestinal mucosa will support a modulation of its functions towards performance and fish health improvement. Here we used a European seabass *ex vivo* model derived from either young juveniles or adults, to evaluate and categorize the functional properties of *Ulva* sp. broken biomass (*Ulva*-BC), together with two commercial products based either on seaweed-derived sulfated polysaccharides or algae-derived beta-glucans. Special focus was given to the immunostimulant and antioxidant capacity, but also on the intestinal mucosa integrity and homeostasis promotion testing for a differential response according to fish size.

**Material and methods**

To infer if fish respond similarly in different stages, we used an optimized *ex vivo* gut mucosal screening model based on intestinal explants, to assess the transcriptional responses of small (27 - 44 *g*) and large (152 - 180 *g*) European seabass to the ingredients. Fish were fasted for 24 hours and anesthetized for explants excision from the anterior intestine. These were then incubated with a commercial-like dosage of each target ingredient for 4 hours. To determine size-specific effects, tissue response was evaluated by quantitative real-time PCR (qPCR) of genes associated with immune response (*il1b*, *il8*, *tnfa*, *mmp9*, *mmp13*), antioxidant defense (*sod1*, *gpx1*, *ptx*) and epithelial integrity (*tjp1*, *ocl*, *cldn5*, *cldn12, imuc*). Gene relative expression was calculated, and levels were then compared between small and large fishes.

**Results**

We observed that the gut mucosa of small seabass exhibited a different expression profile of immune-related genes compared to larger individuals. In both size groups, the commercial products did not significantly upregulate immune gene expression. Instead, only slight activation or maintenance of immune markers was observed, suggesting a potential modulatory rather than a strong immunostimulatory effect. On the other hand, *Ulva*-BC induces a robust immune response, mainly in larger fish (with higher expression of *il1b*, *il8*, *mmp9*), and to a lesser extent in smaller fish (mainly through *il1b* and *mmp9*). This highlights its potential for enhancing immunocompetence during grow-out phases. No differences were observed in antioxidant responses between small and large fish. Interestingly, molecular markers associated with epithelium integrity and homeostasis were either not affected or, in some cases, downregulated following the inclusion of *Ulva*-BC and the product with seaweed-derived sulfated polysaccharides. On the other hand, the algae-derived B-glucan enriched ingredient stimulated the expression of mucosa integrity markers (*ocl*, *tjp1*, *imuc*, *cldn5*), although at a lower magnitude. This indicates that although all ingredients were algae-derived, their effects differ in both application and intensity depending on fish life stage

*(Continued on next page)*

**Conclusion**

Based on these findings, algae-derived ingredients have a promising, yet stage-specific, role in enhancing European seabass health. While the commercial products showed only a mild immunostimulatory effect, the *Ulva*-BC showed strong potential to boost immunity, especially in larger, more mature fish. This makes it particularly useful during the grow-out phase, when fish face more environmental stressors. The different responses to the ingredients highlight a critical distinction: not all algae-based products work the same way. The algae-derived beta-glucan ingredient was especially effective at improving epithelial integrity, while the other ingredients showed little to no effect. These results emphasize the importance of a targeted approach to functional feed development, that align specific bioactive compounds to the fish's developmental stage to improve health and promote sustainable aquaculture.

## Introduction

The transient receptor potential cation channels (TRPV) subfamily of ion channels is crucial in mediating temperature-sensitive physiological processes in fish species. In teleost, *in silico* analyses have identified three to four members of the TRPV subfamily: TRPV1 (TRPV1a and TRPV1b in some species), TRPV4 and TRPV5 (Morini et al., 2022). As global climate change drives elevated water temperatures, concerns have grown over the potential impacts on gonadal development and spermatogenesis. To explore this, we studied how TRPV expression relates to androgens and sperm kinetics in male sea bass during their second year of growth, after being raised in warm water from an early age.

## Material and methods

Characterization of TRPV in European sea bass was made *in silico* by using BLAST tool from NCBI. Gene-specific primers for TRPV and the reference genes —elongation factor 1-alpha (ef1-α) and ribosomal protein L13 (rpL13) — were designed for quantitative PCR. Juvenile sea bass (average initial weight: 14.0±4.1 g) were divided into two treatment groups, each in triplicate for 21 months: (i) a control group (CG) reared at ambient seawater temperature (40°08′15″ N; 0°10′12″ E), and (ii) a high temperature group (HTG), maintained at 3–4 °C above the control temperature. To assess the reproductive influence of temperature a total of 10 fish (5 males each group) were sampled at three key stages of gonadal development: early recrudescence (October), late recrudescence (December), and final maturation-spermiating testes (February and March). Circulating blood levels of testosterone (T) and 11-ketotestosterone (11-KT) were measured by a conventional enzyme immunoassay (EIA), and TRPV expression from testes were measured monthly by quantitative PCR, while sperm kinetics (MOT, MOTp VAP, VCL, and VSL) were evaluated using Computer-Assisted Sperm Analysis software during the spermiating season, in March.

## Results and discussion

Our investigation showed for the first time the presence and expression of four paralogous genes belonging to the TRPV subfamily in European seabass: TRPV1a, TRPV1b, TRPV4, and TRPV5.

In October, TRPV1b and TRPV4 showed significantly higher expression levels in the HTG (average monthly temperature: 25.8 ºC) compared to the CG (21.7 ºC), suggesting the existence of a temperature threshold for these genes in sea bass. Additionally, different expression patterns were noted within the HTG: TRPV1a and TRPV1b showed its maximum expression in October, whereas TRPV4 and TRPV5 exhibited a cyclical expression pattern, reaching its maximum expression at the onset and the end of the reproductive season. A principal component analysis (PCA) revealed a distinct clustering of TRPV and circulating steroids levels under high rearing temperature, suggesting that male reproduction is a temperature-sensitive process involving these receptors. By the end of the reproductive period, correlations between gene expression, circulating steroids levels and sperm kinetics highlighted the involvement of TRPV in reproductive performance: the paralogs TRPV1a and TRPV1b displayed an antagonistic role in sperm function, while TRPV1a was associated with boosted sperm performance, high expression levels of TRPV1b were clearly correlated with the reduction of sperm kinetics (Fig. 1A, B). Given its correlation with T and 11-KT (Fig. 1B), we suggest that TRPV1b might be involved during sexual maturation and early stages of spermatogenesis whereas TRPV1a seems to be critical during spermiation. Although a positive correlation was observed between TRPV1a, TRPV4 and VAP in CG (Fig. 1A), the increased temperature modified this interaction, leading TRPV4 to align with TRPV1b, resulting in a negative impact on spermatozoa velocity (Fig. 1B).

*(Continued on next page)*

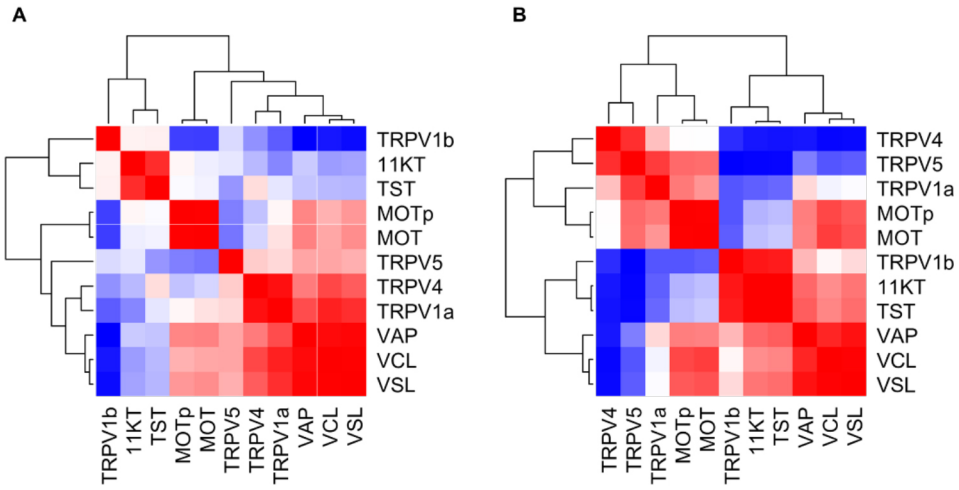

Figure 1. Clustered heatmap based on Pearson correlation analysis ($p < 0.05$) of sperm quality, blood steroids level and gene expression in gonad of full spermiating sea bass males from CG (A) and HTG (B). Red indicates a positive correlation while blue indicates a negative correlation. The darker the colour, the greater the correlation coefficient.

Overall, our findings suggest the involvement of TRPV in the reproductive physiology of male sea bass and demonstrate that elevated rearing temperatures can alter their function. Nevertheless, additional studies are required to clarify the specific molecular pathways involved in TRPV-mediated responses and to better understand their impact on reproductive outcomes in a global warming scenario.

Presenting author email: anafm@um.es
2- Mediterranean Algae. Av. Elche 157, Alicante, 03008. Spain

## Introduction

The removal of heavy metals and nutrients from port waters remains a critical environmental challenge. In this line, macroalgae bioremediation has demonstrated potential to enhance water quality and support biodiversity. Moreover, when integrated with ICT tools, such as carbon footprint tokenization, blockchain and IoT monitoring, it also generates economic incentives for sustainable practices. However, broader implementation still demands evaluation of regulatory, economic and operational feasibility.

## Material and Methods

This pilot study, conducted at the Port of Alicante in collaboration with Mediterranean Algae company, tests the use of *Ulva sp*. cultivation combined with ICT tools for port water treatment. The system uses circulating tanks to grow macroalgae while monitoring environmental parameters. It aims to enhance water quality and address climate change impacts by providing Blue Carbon Credits.

The pilot consists of three 2000L tanks where *Ulva sp*. is cultivated to treat port water through continuous circulation and bioremediation in a closed system. IoT sensors monitor key parameters, while a digital platform enables real-time system optimization. $CO_2$ absorption is tracked via blockchain to generate carbon credits, creating economic incentives. *Ulva sp*. is analyzed for contaminants and explored for reuse, linking bioremediation with waste valorization and scalability.

## Discussion

The pilot will integrate macroalgae and digital technologies to improve water bioremediation and promote circular economy models through Blue Carbon Credits generation. It will identify native algae potential, develop new algae-based products and enhance public-private collaboration. A replicable protocol will be developed to support future implementation and scalability in other regions.

[(2)]ICTA, Universitat Politècnica de València, Camino de Vera s/n, 46022, Valencia
E-mail: isferse1@tal.upv.es

## Introduction

White shrimp (*Litopenaeaus vannamei*) is a very important aquaculture species worldwide. These crustaceans have a very short shelf-life, mainly due to microbial spoilage and also to melanosis, the latter being a major problem for shrimp marketing. To prevent melanosis, sulphites are commonly used. However, they are associated with allergic reactions, and consumers are increasingly seeking additive-free foods. There is a growing interest in natural alternatives that prevent melanosis and can extend shrimp shelf-life. Essential oils or their compounds have been studied in different forms of application, such as in active films or by spraying or immersing shrimps in their solutions, demonstrating the great potential of these compounds to delay melanosis. The objective of this work was to study the effect of the carvacrol (free or encapsulated in montmorillonite) supplemented in shrimp feed, on the prevention of melanosis.

## Materials and methods

Three different shrimp feed formulations were studied: A control diet (**Control**, 33% crude protein and 10% crude lipid), the same diet supplemented with 150 mg/kg of carvacrol in free form (**Car_Free**), and the last one supplemented with 150 mg/kg of carvacrol encapsulated in montmorillonite (**Car_MM**).

Before starting the feeding test, all shrimp larvae were acclimated to indoor rearing conditions for four weeks and fed a standard diet. The trial began with shrimp weighing approximately 1.8 g. Three aquariums were used per diet, each containing 25 specimens. The shrimp were hand-fed three times a day for a total of 78 days. After this period, the shrimp were slaughtered and stored in refrigeration for 10 days. The melanosis was evaluated on days 0, 3, 6, and 10 of storage., by visual inspection by 10 trained panellists. The scale of melanosis used was: Absent=0; Mild=up to 20 %; Moderate=20-40 %; Notable=40-60 %; Severe=60–80 %; Extensive=80–100 %.

## Results

Melanosis scores are shown in Fig 1. The highest scores were obtained in shrimps fed the control diets for all storage days, except for day 0, where no melanosis was observed. The main differences were observed on days 3 and 6, with the sample fed the diet with encapsulated carvacrol (Car_MM) presenting the lowest scores, although there were no significant differences between Car_Free and Car_MM. At day 10 the differences between samples were smaller, with no significant differences between them.

## Conclusion

Carvacrol encapsulated in montmorillonite shows potential as a feed ingredient to prevent melanosis; however, at the concentration used in this work, the effect is not enough to prolong shrimp shelf-life. Further studies with higher concentrations should be carried out to determine if this compound could prevent the problem of melanosis.

*(Continued on next page)*

## Introduction

The fishing sector, including aquaculture, is one of the food production sectors that has experienced the greatest growth in recent years. The high production volume leads to the generation of a large amount of by-products. In the case of sea bream (*Sparus aurata*), the filleting process generates by-products including skin, bones, and heads, which are often not properly utilized and are discarded (Rathod et al., 2024). Fish is an essential food in the diet, so it is important to promote its consumption, particularly among population groups with low fishery product intake, such as children. Fish nuggets represent an attractive alternative due to their ease of consumption and sensory acceptability. In this context, sea bream nuggets made with fishery by-product meal emerge as an innovative option, utilizing fishing industry waste to improve sustainability and nutritional value. Consumers' search for fresh products makes the marketing of nuggets on refrigerated shelves attractive. However, the commercial potential of these products is affected by their shelf life, which is limited primarily by microbial growth.

The objective of this study was to study the microbial and sensory quality evolution of sea bream nuggets which contained fishery by-products, packaged in a modified atmosphere in cold storage.

## Materials and methods

Cleaned and gutted sea breams were filleted, using the muscle to make the nuggets and the by-products to obtain the flour. Fish by-products were boiled in water, drained, pressed with cheesecloth, grounded, dried at 60 °C, milled and sieved. Different nuggets formulations were developed: C (control samples with sea bream muscle, salt, potato flakes, egg white and ice), B (samples C where part of the seabream flesh was replaced by 6 % of fish by-products meal). The batter ingredients were: salt, xanthan gum, baking powder, baking soda and water. Breadcrumbs were used to coat the nuggets.

Samples were packaged in trays in modified atmosphere (MAP) (70% $CO_2$ and 30% $N_2$) and stored under refrigeration (4 °C) during 21 days. Microbiological analyses (aerobic mesophilic bacteria and *Enterobacteriaceae*) were performed on days 0, 3, 7, 10, 14, 17, and 21 of storage.

## Results

The mesophilic and *Enterobacteriaceae* counts in the two types of sea bream nuggets are shown in Fig. 1. The initial level of mesophilic bacteria was below 4 log CFU/g for both formulations, indicating a good hygienic-sanitary quality of the freshly prepared samples. Counts of these microorganisms increased progressively during storage. From day 14 onwards, both samples exceeded the acceptable limit, showing counts greater than 7 log CFU/g.

Regarding the evolution of *Enterobacteriaceae* growth, a significant increase was observed during storage. In this case, the trend is similar to that for the growth of mesophilic microorganisms, exceeding the acceptable limit from day 14 onwards, with counts greater than 3 log CFU/g.

The incorporation of by-product meal in the formulation did not imply significant differences in either the mesophilic or *Enterobacteriaceae* counts.

*(Continued on next page)*

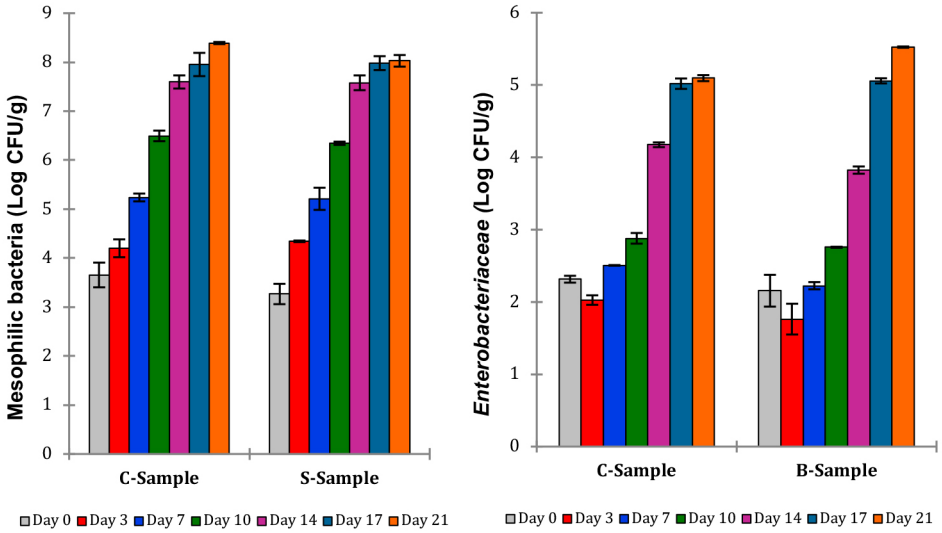

Fig. 1. Mesophilic and *Enterobacteriaceae* counts in the two types of sea bream nuggets (control (C) and by-product (B)) during the 21 days of storage. Error bars represent standard deviations.

## Conclusions

Sea bream nuggets with or without by-products packaged in MAP in cold storage would have a shelf life of 10 days. According to these results, incorporation of by-product meal in nuggets formulations does not affect the products' shelf life.

# ADVANCES IN THE CULTIVATION OF STRIPED RED MULLET *Mullus surmuletus*: COLOR CHANGE INDUCTION

B. Fernández[1], M. J. Brianes[1], L. Costa[1], M. Vázquez[2], R. Caamaño[2], S. Cabaleiro[2] and C. Gabín-Sánchez[1]

[1] Centro de Investigacións Mariñas de Galicia (CIMA). Pedras de Corón, s/n. 36620 Vilanova de Arousa (Pontevedra). Spain
E-mail: bernardo.fernandez.souto@xunta.gal
[2] Centro Tecnológico del Clúster de la Acuicultura (CETGA). Punta Couso s/n. 15965 Ribeira (A Coruña). Spain

Introduction

The main objective of the SALROC research project is to contribute to the diversification of marine fish farming in Europe by optimizing farming techniques for the striped red mullet (*Mullus surmuletus* Linnaeus, 1758). This project, funded by the Xunta de Galicia, has been running since 2024 at CIMA (Centro de Investigacións Mariñas de Galicia) and CETGA (Centro Tecnológico del Clúster de la Acuicultura).

During the initial investigations of the SALROC project, it was found that striped red mullets housed in CETGA adopted differents color shades depending on the color of the inside of the tanks (black or green) where they were housed. In CIMA tanks, with white interior walls, the specimens progressively lost their pinkish-reddish coloration, taking on whitish tones. To study the effects of tank color on the body color of the striped red mullet, raffia nets of differents colors was placed on the bottom of the CIMA tanks.

**Material and methods**

This experiment was carried out in three cylindrical tanks, each 1.10 m in diameter, with a surface area of 1 $m^2$ and a volume of 0.5 $m^3$, located at the CIMA. Twelve individuals, captured in the Ría de Arousa (NW Spain), were housed in each tank. The tanks were originally designed for mollusc culture but were adapted to accommodate flatfish and benthic fish (Fernández and Brianes, 2025). Bottom refuges made from oyster baskets were installed at the bottom of the tank as Environmental Enrichment (EE) elements (Fernández *et al*., 2025).

The interior walls and the background of the CIMA tanks were white, which allowed for various color change tests. In February 2025, to study the effects of tank color on the body color of striped red mullets, to verify the intensity and speed at which these color changes occurred, and to determine their possible reversibility, plastic raffia nets of different colors (green, brown and black) were temporarily placed on the white bottom of the tanks at CIMA.

**Results**

Following the placement of raffia at the base of the CIMA tanks, a rapid and significant alteration in the fish's pigmentation was observed. The intensity of the colouration increased proportionally with the darkness of the raffia substrate, with individuals exhibiting vivid reddish hues when black raffia was utilised, and comparatively less intense reddish tones when green or brown raffia was employed (Figure 1). Additionally, the sclera of the striped red mullet's eyes exhibited a reddish coloration (Figure 2). These chromatic changes occurred swiftly, within less than five minutes, and were reversible; upon removal of the coloured raffia, the specimens reverted to a pale body pigmentation and the sclera returned to its white appearance within minutes., showing an amazing camouflage power ("*the chameleon of the sea*").

Being able to easily induce the camouflage ability of striped red mullets with their surroundings so that they quickly adopt a more "natural" color is of great importance for their potential cultivation, since an appropriate color of the fish (close to that typical of wild specimens) is one of the characteristics that could facilitate the future commercialization of this species.

**Conclusions**

The integumentary coloration of fish (and other animals) is primarily driven by the presence of various types of chromatophores, which in some cases allow them to adapt chromatically to environmental tones and patterns through mimicry or camouflage (Fujii, 2000). Studies on changes in fish color patterns are relatively abundant, especially in flatfish, but not in the case of the striped red mullet (Tokac *et al*., 2013).

*(Continued on next page)*

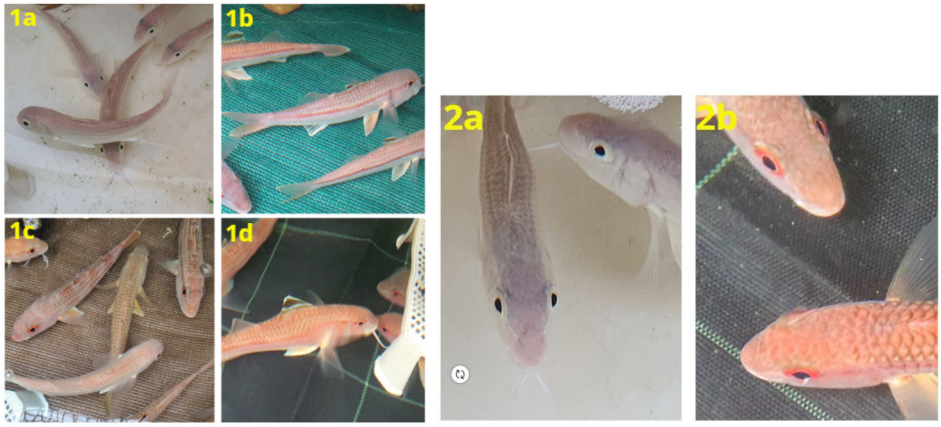

**Figure 1**: Striped red mullets on white (1a), green (1b), brown (1c) and black (1d) backgrounds. **Figure 2**: Detail of the change in color of the sclera of the eye of the striped red mullets in a tank with a white background (2a) and after placing a black raffia on the bottom of the culture tank (2b).

This study demonstrates for the first time a phenomenon of pigmentation change in striped red mullet housed in culture tanks, opening up the possibility of applying camouflage-inducing techniques by changing the color of the bottom and/or internal walls of the culture tank, either temporarily (by placing raffia on the bottom) or permanently (by painting the interior of the tank). Color changes toward more consumer-friendly hues could be induced by using dark tanks throughout the entire culture cycle of the species or by temporarily housing them (a few days before marketing) in dark-colored tanks. This experience also opens the door to future research that could determine the optimal color for culture tanks for this species from an animal welfare perspective.

## Introduction

The blue crab (*Callinectes sapidus*) invasion in the Western Mediterranean Sea has strongly impacted Manila clam (*Ruditapes philippinarum*) aquaculture (Chiesa et al., 2025; Prado et al., 2024). Manila clam aquaculture in land-based ponds is an alternative that allows us to avoid the risk of predation from the blue crab. Pond integrated multi-trophic aquaculture (IMTA) appears as a further step to increase productivity through the efficient recycling and reuse of nutrients. Manila clam growth in IMTA earthen experimental ponds in the Ebro delta has shown to result in improved growth performance compared to Manila clam pond monoculture. Higher particulate organic matter content in the water due to the fish fed supplied and microphytobenthos resuspension by the fish in the pond may explain the big differences in clams growth performance.

## Materials and methods

A Manila clam monoculture experiment was carried out in an earthen pond (20 m x 5 m) covered with a thin layer of sand filled with seawater up to 0.30 m; seawater from Alfacs Bay (Ebro delta, Western Mediterranean) nearshore waters was pumped at a rate of one renewal per day (30,000 L/day). The clams were seeded (16.5 ± 1 mm) in March 2020 at a density of 50 clams per $m^2$, harvesting was conducted in November 2021. The pond was covered with a sunshade netting, during summer months, to reduce the growth of macroalgae and decrease seawater temperature. Physicochemical parameters were measured twice per day, morning and afternoon, chlorophyll-*a* concentration was analyzed daily, clams growth was measured once per month during the whole period.

A second experiment was carried out at the same earthen pond, and a duplicate pond next to it, where the Manila clam culture was part of an integrated multi-trophic system that also included flathead grey mullet (*Mugil cephalus*) and oysters (*Ostrea edulis* and *Crassostrea gigas*). Seawater from Alfacs bay was pumped at a rate of 96,000 L/day. The water depth was 1 m. In this second experiment the ponds were not covered with sunshade nets. Mullet was fed with fish feed. Clam seeding (18.7 mm ± 1 mm) was conducted in November 2024 at a density of 30 clams per $m^2$, 1,000 individuals of *O. edulis* and 1,000 individuals of *C. gigas* per pond were seeded at the same time. Physicochemical parameters were measured daily, chlorophyll-*a* concentration was analyzed twice per week, clams growth was measured in March, May, June and August 2025.

To sample each pond, we collected the clams present in 10 replicates using 25 × 25 cm quadrats. Clams per quadrat were counted, the shell length of the clams was measured with a caliper to the nearest 0.1 mm. Clam biomass was measured as wet weight, including the shell and flesh dry weight. The flesh dry weight was measured after drying for 48 h at 60 °C. Growth performance was determined as specific growth rate according to the equation $SGR= ((\ln L_t - \ln Lt_0)/(t-t_0)) \times 100$, where $Lt_0$ is the initial length, $L_t$ is the final length, and $t\text{-}t_0$ is the elapsed time in days as in Zanella et al. (2025) using length instead of weight.

## Results

The ranges and means (min-max, mean) of physicochemical parameters during the first experiment were the following, temperature: 5.7 -29.8 °C, 19.2 °C; practical salinity: 22.1-38.3, 35.6; oxygen concentration: 3.0-11.7, 6.3 mg/L; pH: 7.1-8.5, 7.9. During the second experiment, the ranges and means in pond 1 were the following, temperature: 9.7-29.5 °C, 17.6 °C; practical salinity: 32.7-37.5, 35.2; oxygen concentration: 2.3-9.6 mg/L, 6.6 mg/L; pH: 7.6-8.5, 8.1; and temperature: 9.4-29.3, 17.5; practical salinity: 32.4-37.9, 35.1; oxygen concentration: 2.8-9.4 mg/L, 6.5 mg/L; pH: 7.5-8.9, 8 in pond 2.

*(Continued on next page)*

Chlorophyll-*a* concentration during the first experiment at the water catchment point in Alfacs Bay was 3.8 ± 1.6 µg/L, while the concentration at the pond inlet was only 0.5 ± 0.1 µg/L (March 2020-February 2021), therefore from March to November 2021 we moved the water catchment point to a small lagoon closer to the experimental pond where chlorophyll-a concentration was higher (1.4 ± 1.6 µg/L). During the second experiment, chlorophyll-*a* concentration at the inlet was 0.8 ± 1.0 µg/L in pond 1 and 0.9 ± 1.1 µg/L in pond 2. Chlorophyll-*a* concentration at the outlet of the ponds was slightly higher, 1.5 ±1.7 µg/L in pond 1 and 1.0 ±1.4 µg/L in pond 2.

Clams growth performance during the period from March 2020 to November 2021 was 0.1 (%/day) starting from a shell length of 16.5 ± 1 mm (mean ± SD) and reaching 29.4 ± 3.1 mm after 618 days; while for the second experiment from November 2024 to August 2025 it was 0.21 in pond 1 and 0.20 (%/day) in pond 2, starting from a shell length 18.7 ± 1.1 mm, reaching 32.7 ± 4.6 mm in pond 1 and 32 ± 3.3 mm in pond 2 after 272 days of growth.

**Discussion and conclusions**

Pond integrated multi-trophic aquaculture (IMTA) has shown to result in improved Manila clam growth performance under similar culture conditions in comparison to Manila clam pond monoculture. Reduced clam seeding density and increased water flow during the IMTA trial may have also contribute to obtain double growth performance in IMTA in comparison to the clam monoculture, but the supply of fish fed together with the microphytobenthos resuspension seem to have contributed to this improved results since chlorophyll-*a* concentration at the outlet of the IMTA ponds was higher than the concentration at the inlet.

**Introduction**

The protozoan parasite *Perkinsus olseni* is a global threat to bivalve mollusks, with a deleterious effect in growth performance as well as reproduction capacity[1], including economically valuable species such as *Ruditapes decussatus* (RD), *Ruditapes philippinarum* (RP), and *Venerupis corrugata* (VC), the most economically valuable species of clams in Portugal.

This study was designed to mimic a natural infection and aimed to investigate the response of these three clam species to the parasite. Seed (5-7 mm length) was exposed with two different concentrations of parasite to identify the differential susceptibility of the species to the disease. The gene expression profile at short and long term was determined by RNA-Seq and also the microbiota community composition was evaluated.

**Material and methods**

After isolation of parasite hypnospores[2], two different concentrations were added to tanks (Low Infection (LI) treatment $5x10^5$ cells; High Infection treatment (HI) $5x10^6$ cells). After 48 hours, water was renewed, and the progression of the infection was followed for one month. Samples were taken over four time periods (48 hours, 7-, 14- and 30-days post exposure) to assess short and longer-term responses. Presence and prevalence of parasite over time was evaluated by qPCR[3]. Also, RNA was extracted from samples of 48 hours and 30 days' post exposure. The microbiota community was evaluated by the sequencing of the V3-V4 region of the 16S after isolating the DNA from the whole clam at 30 days' post-exposure in control and HI treatment to verify if the infection had an impact on the community.

**Results**

While in HI treatment all clams became infected, in LI treatment the prevalence indicates a higher predisposition of RD and RP to the disease (97.5% and 76.6% prevalence, respectively), followed by VC (74.4% prevalence). Regarding the parasite load of infected individuals, results showed significant differences in the infection intensity of each clam species to the parasite, with RP showing higher parasite load throughout the experiment. Conversely, VC demonstrated a lower susceptibility to the parasite, with lower parasite load observed at short and long term while RD showed an intermediate response, falling between the other two species (Figure 1).

At transcriptomic level, all species seems to be compromised by the infection at both timepoints, functions such as immune system, reproduction and cellular proliferation were compromised, and just some functions such as dopamine norephrine biogenic amine related to stress responses and regulation of feeding networks were up-regulated[4].

Regarding microbiota community, there is no clear impact on the composition after infection, but some groups seemed to be modulated by the parasite infection. On the other hand, there is a clear separation of the microbiota composition among species (Figure 2).

In conclusion, these findings highlight the variable response of three clam species to *P. olseni*, suggesting that VC may be less susceptible to the parasite, while RP may be the most susceptible. This study provides valuable information for understanding and managing the impact of *P. olseni* on clam populations.

# SPECIES SELECTION OF MACROALGAE FOR APPLICATION WITHIN IMTA IN OFF COAST AREAS OF THE MEDITERRANEAN SEA

J. M. Valero-Rodríguez[1]; P. Sanchez-Jerez[2], V. Fernandez-Gonzalez[2*]

[1] University of Bergen, Department of Biological Sciences, Bergen, Norway

## Introduction

Aquaculture has rapidly expanded in the Mediterranean Sea in the last decades, with species like European seabass, gilthead seabream, mussels, oysters, and clams dominating production (FAO, 2024). Concerns about environmental impact, particularly waste deposition, have led to the exploration of integrated multi-trophic aquaculture (IMTA) as a more sustainable approach (COM/2021/236). Thus, the inclusion of macroalgae in IMTA systems has always had strong support from the scientific community. The combination of species present in the area and the opportunities that these entail, bring about a best option for the industry.

The main aim of this study is to overview the outline of adequate macroalgae species with potential for IMTA in the four main geographical areas of the Mediterranean Sea and their value as secondary product such as biometabolite producers.

## Material and Methods

Information used to design this study was obtained from conference papers, indexed journals and concrete literature found in databases such as Science Direct, Google Scholar or Scopus using PRISMA methodology. Subsequently, a SWOT analysis was used to evaluate candidate macroalgae species in the Western, Central and Eastern Mediterranean and Adriatic Basin for their presence and potential use in IMTA systems. The 'Strengths and weaknesses' category in this case include inner traits related to species biology such as culture chances related to natural distributions in waters of a country . The 'Threats' section is defined by specific critical traits that could either endanger or promote deleterious consequences for the environment of the aquaculture production nearby. One of such situations involve the appearance of introduced species or bloom-inducing genera with deleterious consequences for fish production. Finally, the last section was constructed around the interest or commercial potential of the species found ('Opportunities').

*Table 1. Summary of the SWOT analysis for potentially cultivable species of the Western, Central, Eastern Mediterranean, and Adriatic Basin.*

| Region | Promising Species | Cage Presence | Strengths | Weaknesses | Opportunities | Threats | Notes |
|---|---|---|---|---|---|---|---|
| Western Mediterranean | *Ulva rigida, Gracilaria gracilis* | Yes | + | + | ++ | + | High growth, polysaccharides |
| Adriatic Sea | *Ulva lactuca, Chaetomorpha linum Gelidium spp.* | Yes | ++ | + | + | + | Good growth, antioxidant activity |
| Central Mediterranean | Ulva spp. *Gracilaria spp. Chaetomorpha linum* | Likely | ++ | + | ++ | + | Bioactive peptides, rapid growth |
| Eastern Mediterranean | *Ulva fasciata, Gracilaria* sp. | Yes | ++ | + | +++ | + | Protein-rich, IMTA trials support |

*(Continued on next page)*

**Results & Discussion**

This study analysed data of 162 algae, categorised into 42 green, 50 brown and 70 red algae. The critical components to be discussed about algae selection for IMTA systems refer to the selection system in the four areas of the Mediterranean Sea. The analysis of threats and opportunities is pertained to the present and even more importantly, also the future environment. Determining the importance of these factors by SWOT analysis gives a clearer view of the chances of success of algae cultures embedded in IMTA production systems. Thus, the selected genera for Western, Central, Eastern Mediterranean, and Adriatic Basin encompass a diverse range of macroalgal species (Table 1).

The species identified in our study craft primary and secondary metabolites, some indispensable for internal growth and metabolism, while others exhibit substantial potential for broader applications in various biological processes. Algal metabolites, spanning polyphenols, alkaloids, terpenes, polysaccharides, fatty acids, sterols, lactones, proteins, and peptides, embody diverse structural and functional classes, each wielding significant biological activities.

The selected macroalgae according to SWOT results belong to genus such as *Chaetomorpha*, *Ulva*, or *Gracilaria,* which are also found among fouling communities, collectively enrich the algal tapestry within aquatic farming facilities. They exhibit unique biochemical characteristics, making them promising subjects for biotechnological exploration.

The convergence of low trophic level species selection and region-specific macroalgae cultivation represents a pioneering step towards a more sustainable and adaptive future for Mediterranean aquaculture. These results provide valuable insights for stakeholders and decision-makers, aiding in implementation of IMTA systems and the sustainable development of aquaculture in the Mediterranean.

## Introduction

In order to promote sustainable aquaculture practices, fishmeal and fish oil from aquafeeds are being progressively replaced with plant-based alternatives. However, this substitution may negatively affect carnivorous species, such as rainbow trout (*Oncorhynchus mykiss*), especially during early developmental stages (Lazzarotto et al., 2018). The underlying molecular mechanisms of these effects are not yet fully understood. To shed light on this, the aim of this study was to characterize the temporal evolution of the mRNA abundance of amino acid sensing systems in the gastrointestinal tract (GIT) and of appetite-regulatory genes in the brain of rainbow trout from the first feeding, as well as to evaluate the putative modulation of such temporal profiles of a plant-based diet.

## Materials and methods

Rainbow trout juveniles were fed two experimental diets from the first feeding until 100 days: a control diet similar to a commercial feed (containing a mix of fishmeal and plant meal), and a 100 % plant-based diet. Samples of the GIT and brain were collected on days 0 (before the first meal) and 2, 5, 10, 30, and 100 post-initiation of feeding. The abundance of genes related to amino acid sensing and appetite-regulatory hormones in the GIT and to feed intake regulation in the brain was quantified by quantitative PCR (qPCR).

## Results and discussion

Trout fed the plant-based diet exhibited lower feed intake levels compared to those fed the commercial-like diet, resulting in reduced final growth. This difference may be attributed to a lower palatability of the plant-based diet, possibly due to anti-nutritional factors or differences in nutrient composition, or to a putative alteration of nutrient sensing mechanisms and feed motivation, ultimately affecting central regulation in the long term.

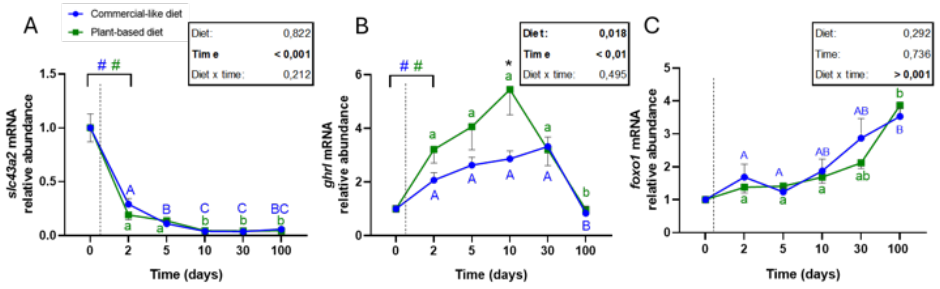

Figure 1. Temporal expression patterns of three of the studied genes in the GIT (A and B) and brain (C) of rainbow trout fed with either a commercial-like or a plant-based diet diets during the first months of life. Figure shows the relative mRNA abundance before the first feeding (time 0) until 100 days after being fed. The significant effect of time ($P < 0.05$) within each dietary condition is indicated by uppercase blue letters (commercial-like diet) and lowercase green letters (plant-based diet), while asterisks (*) denote significant differences ($P < 0.05$) between the two diets at a given time (two-way ANOVA). Pound symbol denote significant differences ($P < 0.05$) between day 0 and day 2 (Student's t-test).

*(Continued on next page)*

Regarding amino acid sensing mechanisms, the commercial-like diet induced an increase in the mRNA abundance of one of the studied receptors (*tas1r2a*) at the onset of feeding, although no major changes were then observed throughout development. As for amino acid transporters, the first feeding with either a commercial-like or plant-based diet modulated the mRNA abundance of *slc43a2* and *slc1a5*. Subsequently, increasing mRNA abundance over time was observed for *slc6a19*, *slc15a1*, and *slc1a1*, while decreasing mRNA levels at early stages were found for *slc7a9* and *slc43a2* (Fig. 1A). No major differences in the temporal mRNA abundance profile were observed between diets (except for *slc1a5*).

The onset of feeding (with one or both diets) caused a significant increase in the mRNA levels of almost all gastrointestinal hormones (*ghrl*, *gcg*, *pyy*) (Fig. 1B). At early developmental stages, an increase in mRNA abundance was observed for all hormones, which may reflect the need to regulate feeding through the overexpression of appetite-regulating hormones. However, a decrease in abundance was observed at late stages, which could be attributed to more precise hormonal regulation due to the maturation of these mechanisms.

At the central level, all neuropeptides exhibited significant changes at the onset of feeding, with one or both diets. After the initial feeding, *npy* and *cartpt* (particularly with the control diet) increased progressively throughout development, whereas *agrp* and *pomc* showed a decreasing trend over time. Additionally, the expression of key components of integrative signalling pathways (*prkaa2*, *mtor*, *creb1*, *foxo1*) increased during growth (Fig. 1C), although their abundance was differentially modulated depending on the dietary treatment. Furthermore, no major differences between diets were observed, except for *mtor*.

**Conclusions**

This study provides the first description of the mRNA abundance of appetite-regulating mechanisms in the GIT and brain of rainbow trout from first feeding up to 100 days. The results indicate distinct temporal gene expression patterns in both tissues, with almost no significant dietary (commercial-like *vs*. plant-based diet) effects during early developmental stages. This suggests that reduced feed intake and growth impairments associated with vegetable diets may be due to other physiological mechanisms. These findings are essential for optimizing feeding strategies in sustainable aquaculture.

## Introduction

Fishmeal (FM) is the main cost driver in shrimp aquaculture, accounting for 50–70% of total production costs. Previous studies have demonstrated that *Penaeus vannamei* can tolerate partial FM replacement without compromising growth performance. Additionally, biofloc technology (BFT) provides a nutritional supplement and enhances shrimp immunity. This study aimed to evaluate the impact of FM substitution with alternative protein sources in shrimp diets on the microbial composition of biofloc, and to explore potentials interaction with intestinal microbiota, growth performance and product quality.

## Material and Methods

Six experimental diets were tested in triplicate, featuring either 92% or 100% replacement of fishmeal (FM) with alternative protein sources of animal origin (A92, A100), plant origin (P92, P100), or a combination of both (AP92, AP100). All diets were isoproteic (38% protein) and isolipidic (10% fat). Shrimp were cultured in 1 $m^3$ tanks at 350 individuals/$m^3$ from 2.5 g to 8 g average weight. Growth was monitored biweekly. Biofloc and shrimp gut microbiota were characterized by full-length 16S rRNA gene sequencing (PacBio Sequel II), and amplicon sequence variants were analyzed using QIIME2 and CLR transformation. Sensory quality of shrimp from selected diets was evaluated at 1 and 7 days post-slaughter following ISO standards.

## Results and discussion

Water quality parameters remained within optimal ranges for shrimp culture. Growth performance confirmed that up to 92% FM replacement with animal (A92) and mix of animal/plant protein sources (AP92) is feasible without negative effects. These findings exceed the FM substitution levels reported in previous studies using plant- or animal-based alternatives, or their combination (Aya et al., 2015, Cheng et al., 2002, Hulefeld et al. 2018).

High-quality 16S rRNA gene sequencing data were obtained across all treatments, with a minimum of 81% non-chimeric reads per sample. The most abundant phyla in biofloc bacterial community were *Proteobacteria*, *Patescibacteria,* and *Planctomycetota,* which together represented approximately 68% of the total microbial community. At the taxonomic level of order, *SBR1031* and *Pirellulales* were dominant, accounting for 29% of the overall composition. At the family level, the most prevalent taxa were *Woesebacteria* (14%) and *Pirellulaceae* (12%; (Figure 1A). While the presence of *Proteobacteria* and *Planctomycetota* is commonly reported in biofloc systems (Tanay et al. 2020, Vinasyiam et al. 2025), the detection of *Patescibacteria*, although possible, is often associated with methanogenic archaea. This finding may suggest the formation of microenvironments with reduced oxygen availability within the culture system (Kuroda et al. 2024). Furthermore, the presence of *Woesebacteria* is associated with anoxygenic denitrification (Rajeev et al 2024), and the *Pirellulales* and *Pirellulaceae,* taxa are typically found in low-oxygen environments (Dedysh et al. 2020), supports this hypothesis. In contrast, the intestinal microbiota of shrimp was primarily composed of *Proteobacteria, Planctomycetota, Chloroflexi,* and Actinobacteriota, which together constituted 88% of the microbial community. This profile is consistent with previously reported profiles in shrimp of similar size classes (Zeng et al. 2017). At both the order and family levels, *Pirellulales* and the corresponding *Pirellulaceae* were the most abundant taxa, each representing approximately 18% of the total microbiota (Figure 1B). The composition of the shrimp gut microbiome is known to be strongly influenced by environmental parameters, farming conditions, and the developmental stage of the animals. The consistent dominance of *Pirellula* at both the order and family levels reflects this influence. Moreover, the occurrence of the main phyla is consistent with previously reported profiles in shrimp of similar size classes (Zeng et al. 2017).

*(Continued on next page)*

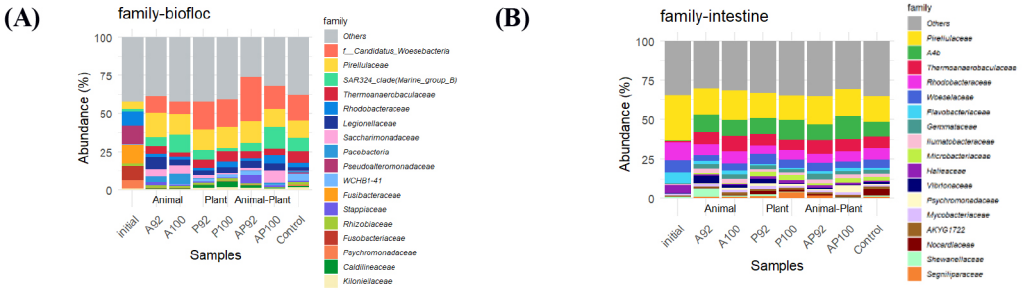

Figure 1: Family taxon level relative abundance at the begging of the experiment (initial) and at the end by treatment (A92, A100, P92, P100, AP92, AP100, Control), evaluated at biofloc (A) and shrimp intestine (B) samples.

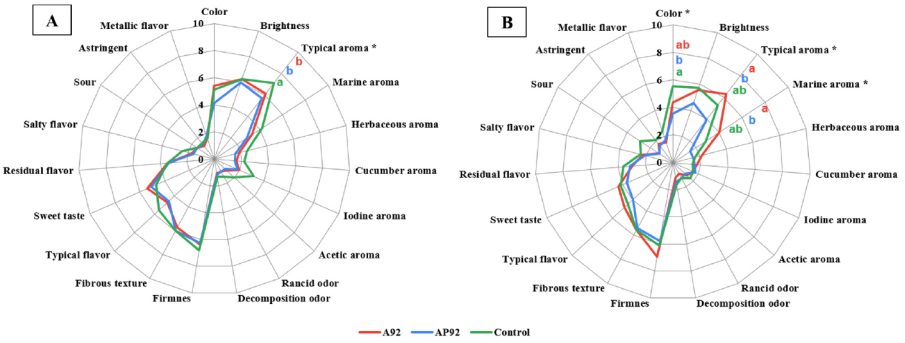

Figure 2: Sensory profile of shrimp fed three diets (A92, AP92, and Control), evaluated at one- (A) and seven- (B) days post-slaughter. (*) symbol represents significant difference between treatments ($p<0.05$).

Regarding alpha diversity, analysis revealed a lower microbial diversity in the initial shrimp samples, based on the Simpson and Shannon indices. However, no significant differences were found at the end of the trial between treatments in either biofloc or shrimp samples. In terms of beta diversity, no statistically significant differences were detected among treatments in any samples.

In relation to the sensory profiles, by day 1, a distinctive shrimp aroma was observed to the Control treatment. Meanwhile by day 7, Control shrimp exhibited the highest color scores, while A92 shrimp obtained the highest marine a typical aroma score (Figure 2. A y B). The melanosis incidence averaged 9% across all treatments initially. However, by day 7, shrimp fed the AP92 diet showed significantly lower melanosis levels (25%) compared to other groups, indicating reduced susceptibility associated with this dietary treatment.

In summary, up to 92% of fishmeal can be replaced with animal or mixed alternative proteins without compromising shrimp growth, water quality, microbiota stability, or sensory quality. Diet composition influenced shrimp-associated microbial communities more than biofloc communities, suggesting host-specific filtering mechanisms. In addition, certain alternative protein diets (AP92) may improve post-harvest quality by reducing melanosis, highlighting the potential of these formulations for sustainable shrimp production.

## Introduction

The incorporation of microalgae and bacterial probiotics into Biofloc Technology (BFT) systems has received growing attention in recent studies focused on *Penaeus vannamei* culture. Supplementation with *Chlorella vulgaris* has been associated with improvements in water quality, growth performance, and overall shrimp health (Swapna et al. 2015). The present study aims to evaluate the potential benefits of such supplementation by characterizing the microbial community structure through metagenomic analysis. Special emphasis is placed on biofloc systems enriched with *C. vulgaris* and a commercial probiotic (*Sanolife PRO-W*, INVE).

## Material and Methods

Two treatments were evaluated (MicroProb) consisting of a biofloc system supplemented with *C. vulgaris* at a concentration of $7 \times 10^6$ cells/mL and an initial dose of a commercial probiotic (*Sanolife PRO-W*, INVE) at 3 g/m³, followed by weekly maintenance doses of 1 g/m³, maintained under a 12:12h light:dark photoperiod; and (Control) a non-supplemented biofloc system maintained under continuous darkness (0:24h photoperiod). The microalgae culture was maintained at 28 °C and 21 PSU salinity, with continuous aeration and illumination ranging from 3,500 to 4,000 lux. The probiotic consisted mainly of *Bacillus subtilis* and *Bacillus licheniformis* spores at a concentration of $5 \times 10^{10}$ CFU/g. *P. vannamei* ($\rho$= 205 animals/m²) were fed twice per day with a commercial feed (LeGoussant). Water quality parameters were maintained within optimal ranges for white shrimp (Van Wyk, 1999) and growth was assessed biweekly via random weight sampling (Kuhn et al., 2010). Biofloc samples were collected at the end of the experiment to ensure representative collection. Shotgun metagenomic sequencing using the Illumina NextSeq 2000 platform. Assembly and binning workflows (metaSPAdes and MaxBin2) enabled reconstruction of metagenome-assembled genomes (MAGs), which were taxonomically classified with GTDB-Tk and functionally annotated via Prokka and DRAM.

## Results and discussion

Water quality parameters remained within optimal levels for white shrimp culture. Shrimp growth performance showed no significant differences between treatments. In the metagenomic analysis, bacteria, archaea, virus, and eukaryotic organisms were identified from the raw reads. However, the MAGs assembly was limited to bacteria and archaea, constraining subsequent analysis. A total of 205 and 210 non-redundant MAGs were recovered from the MicroProb and Control treatments, respectively, with similar proportions of bacterial and archaeal genomes (198 bacterial and 7 archaeal MAGs in MicroProb; 204 bacterial and 6 archaeal in Control). Analysis revealed 26 MAGs exclusive to MicroProb, 28 exclusive to Control, and 19 shared across both treatments. MAG quality metrics, including completeness and contamination, were comparable between treatments. However, MicroProb showed a greater concentration of genomes with intermediate sizes (4–5 Mbp) (Figure 1A) and gene counts (3,000–6,000 genes) (Figure 1B), suggesting a more uniform and potentially functionally balanced microbial community. In contrast, the Control treatment showed a greater number of highly fragmented MAGs and genomes with extreme sizes.

*(Continued on next page)*

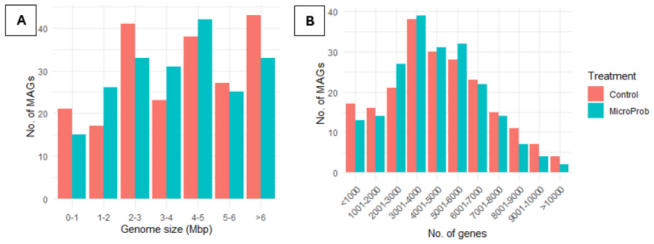

Figure 1: Genome size (A) and number of genes (B) per number of MAGs recovered in each treatment (Red: Control, Blue: MicroProb).

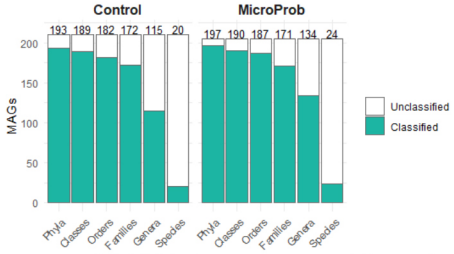

Figure 2: Number of recovered MAGs by treatment (Control, and MicroProb) based taxonomic level classification.

Taxonomic classification was highly effective at higher taxonomic levels, successfully assigning approximately 89% of MAGs to the family level in both treatments. A total of 30 phyla, 56 classes, 91 orders, 118 families, and 24 species were identified. However, a substantial proportion of MAGs remained unclassified at the genus and species levels, indicating the presence of potentially novel or poorly characterized taxa (Figure 2). Dominant bacterial groups shared across both treatments included *Pseudomonadota*, *Bacteroidota*, and *Planctomycetota* (phylum level), *Gammaproteobacteria* (class), and *Pseudomonadales* (order), which are commonly reported in BFT systems (Baliga et al., 2021; Ghonomy et al., 2023). Notably, MicroProb displayed a higher abundance of families such as *Halieaceae*, *Saprospiraceae*, and *Woeseiaceae* (>5 MAGs), which were present only at low abundance in Control. These families have been linked to key ecosystem functions in BFT: *Halieaceae* and *Saprospiraceae* contribute to ammonium removal, while *Woeseiaceae* has been associated with anaerobic denitrification, enhancing nutrient recycling and system sustainability (Rajeev et al., 2024).

Overall, shotgun metagenomic profiling suggests that biofloc supplementation with microalgae and probiotics selectively enriched beneficial and functionally relevant microbial taxa. These changes support the hypothesis that targeted additives can restructure biofloc microbial communities, promoting ecological functions favorable for water quality and shrimp growth performance. A multikingdom analysis will be performed based on the metatranscriptomic assembly, enabling the identification and quantification of a wide range of eukaryotic organisms present in the biofloc.

## Introduction

Shrimp are a highly perishable product due to their rapid microbiological and biochemical spoilage post-harvest. The biofloc system contains a rich microbial community that benefits *Penaeus vannamei* production, modulates its associated gut microbiota, and enhances the immune system, potentially influencing post-mortem freshness. Ensuring high product quality is essential for market acceptance, and the initial microbial load plays a key role in shelf life. This study evaluates the impact of different slaughter methods on the freshness and refrigerated stability of shrimp reared under biofloc conditions, highlighting the interaction between microbiota, slaughter technique, and quality parameters as a basis for optimizing post-harvest practices in intensive aquaculture.

## Material and Methods

Shrimp were cultured at 350 kg/m³ in 3 m³ indoor biofloc tanks and fed commercial feed (LeGoussant) until reaching average weight of 15 g. Water quality parameters were maintained within optimal ranges for white shrimp (Van Wyk, 1999). Four slaughter methods were evaluated: cold thermal shock using refrigerated seawater (-2ºC) (TS, control) (TS was implemented in all slaughter methods); 5 min immersion in refrigerated seawater (0±2.5 ºC) with 50 ppm bleach followed by TS (5BTS); clarification (3–4 h) before 50 ppm bleach and TS (C1BTS); and TS followed by 2 min UV exposure in each side of the shrimp (TSUV). After slaughter, shrimp were packed in sealed plastic bags and cold storage icing was performed over time at 0±2 ºC between ice blocks. A shelf-life study was conducted at 0-, 3-, 6-, 9-, and 12-days *post-mortem*; microbiological count, physicochemical parameters (TVB-N) and Quantitative Descriptive Analysis (QDA) analyses were performed according to the standard ISO 13299 (Sensory profile).

## Results and discussion

Microbiological analysis during cold storage of shrimp revealed significant temporal changes across all bacterial groups. Mesophilic bacteria remained most stable in the C1BTS treatment (~5.2 log CFU/g), likely due to gut-emptying prior to slaughter, while other treatments (TS, 5BTS, TSUV) began with higher counts and declined over time. Enterobacteria increased by ~3 log CFU/g by day 9 before returning to baseline, aligning with previous studies. Pseudomonas spp. declined until day 9, particularly in TS, then slightly rose by day 12, consistent with cold-shock recovery patterns. Spoilage-specific organisms decreased steadily, with initial higher counts in TS and TSUV. Psychrotrophic bacteria increased most markedly in TS, 5BTS, and TSUV (>2 log CFU/g), peaking at ~5.3 log CFU/g, while remaining lowest (~3.5 log CFU/g) in C1BTS. C1BTS consistently demonstrated superior microbial control. Total Volatile Basic Nitrogen (TVB-N) levels, an indicator of spoilage, increased across treatments but remained significantly lower in C1BTS. A strong correlation ($r = 0.987$) between psychrotrophic bacteria and TVB-N suggests that C1BTS reduced microbial growth and enzymatic degradation, thus improving shelf-life.

*(Continued on next page)*

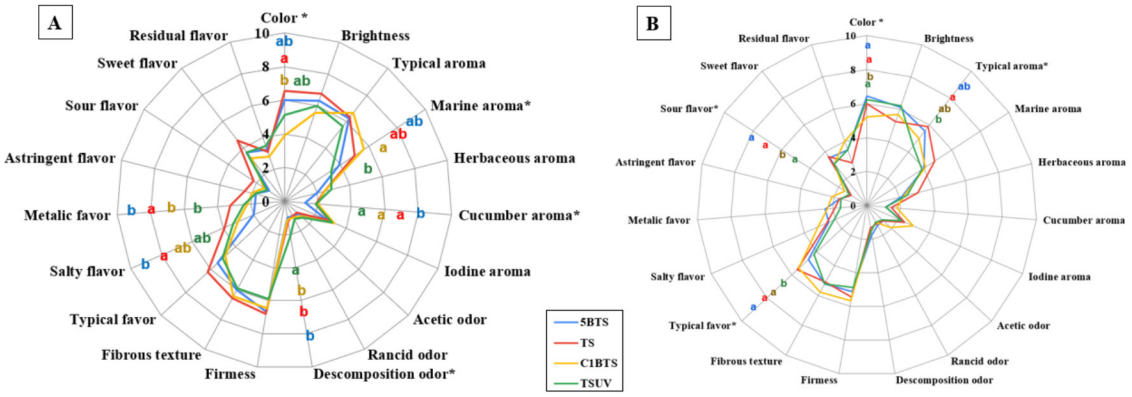

Figure 1: Sensory profile of shrimp slaughtered by 4 methodologies tested (TS, C1BTS, C5BTS and TSUV) * significant differences Letters Homogenius group

QDA analysis was used to assess the sensory quality of shrimp at 1- and 7-day post-mortem. Evaluations were conducted in the tasting room of the Pilot Plant, compliant with ISO 8589:2007.

Shrimp were served whole, boiled, and at room temperature to pre-trained evaluators. The sensory descriptors were established prior to the sessions. Over time, significant freshness-related descriptors such as marine and cucumber aroma, metallic and salty flavor (day 1) disappeared in all treatments, and were replaced by descriptors like typical aroma, typical flavor, and sour flavor (day 7). By treatment, TS stood out for their color, cucumber aroma, and metallic and salty flavors on day 1. And maintained superior scores in typical aroma and flavor and had the lowest sourness by day 7. C1BTS shrimp showed strong marine aroma at day 1 but poor color, which persisted through day 7. Additionally, these samples exhibited the highest sourness on day 7. The 5BTS shrimp with consistently intermediate profiles across all descriptors. TSUV group performed worst overall. They scored lowest in marine and typical aromas and highest in spoilage odor (day 1) and sourness (day 7), suggesting accelerated sensory degradation.

Overall, the C1BTS treatment proved to be the most effective in preserving shrimp quality during refrigerated storage, as evidenced by lower microbial loads, reduced spoilage indicators, and stable organoleptic attributes throughout the study. These findings underscore the potential of C1BTS as a promising approach to extend the shelf life of fresh shrimp under cold chain conditions.

# IMMUNOMODULATORY EFFECTS OF *Salicornia ramosissima* EXTRACTS ON ATLANTIC SALMON ADHERENT LEUKOCYTES: TIME-DEPENDENT FUNCTIONAL AND TRANSCRIPTOMIC RESPONSES

M. Ferreira[1*], M. Fredsgaard[2], S. Rudnyckyj[2], M. Hedegaard Thomsen[2], V. Kiron[1]

[1]Faculty of Biosciences and Aquaculture, Nord University, Bodø, Norway
[2]Department of Energy, Aalborg University, Esbjerg, Denmark
Email: mariana.i.ferreira@nord.no

**Introduction**

The growing demand to adhere to sustainable practices in aquaculture has driven interest in plant-derived immunostimulants. Halophytes, such as *Salicornia ramosissima*, are rich in bioactive compounds that may have immunomodulatory properties and could benefit farmed fish. This study investigated the effects of several *S. ramosissima* extracts on head kidney primary adherent leukocytes from Atlantic salmon (*Salmo salar*), focusing on innate immune responses at both functional and molecular levels.

**Materials and Methods**

Head kidney primary cells were harvested from healthy Atlantic salmon post-smolts maintained at the Research Station of Nord University. Adherent leukocytes, isolated using established protocols, were exposed to five different types of *Salicornia ramosissima* extracts (CAS.EX. 1-5), derived from distinct steps of the extraction cascade. Cytotoxicity was assessed using an MTT assay, and non-toxic concentrations were identified. Adherent leukocytes were exposed to the non-toxic concentration of each extract for either 3 or 24 hours, followed by a challenge with inactivated *Tenacibaculum maritimum*. Phagocytosis and ROS production were measured using Imaging Flow Cytometry. Furthermore, a snapshot of the changes in the transcriptome of the leukocytes was captured to reveal the responses at the molecular level.

**Results and Discussion**

Exposure to CAS.EX. 4 significantly enhanced phagocytic activity and ROS production after 24 h. Transcriptomic analysis revealed distinct early and late-stage immune responses. Within 3 h, CAS.EX. 4 triggered changes in nucleocytoplasmic transport, lysosomal function and lysine degradation. Extending the incubation time to 24 h, activated immune and stress-related pathways, including proteasome function, phagosome formation and autophagy while suppressing cell cycle and DNA repair pathways. These findings suggest that CAS.EX. 4 acts as a potent immunostimulant, enhancing phagocytic activity, stress adaptation, and cellular homeostasis mechanisms in adherent leukocytes from Atlantic salmon. The observed immune modulation and functional outcomes support the potential of *Salicornia ramosissima* extract as a functional ingredient to promote fish health in aquaculture.

## Introduction

The supply of aquatic products for human food predominantly relies on aquaculture, which is now 57% of global production (FAO, 2024). In recent years, annual growth has been 6.6%, but in the West growth has been considerably slower or flatlined.

Fig. 1 shows that growth in Europe (data from Eurostat: http://meta.longline.co.uk) was mainly driven by Norway (salmon) and Turkey (bass and bream). Even if the UK is excluded due to Brexit, the EU APR for the period is -0.1%, compared with 7.9% for non-EU European nations (9% if the UK is excluded from the calculations).

North America is in a similar situation, with a 2008-2022 APR of 0.5% for Canada and 2.3% for the USA. The total production for Europe and North America in 2022 is 4.2 million tonnes, 3% of world production, for 12% of the world population. In Europe, demand for seafood has remained constant, with 22.2 kg per capita $y^{-1}$ in both 2007 and 2024 (FAO, 2010; FAO, 2024) but in Asia, the demand increased from 18.5 kg per capita $y^{-1}$ in 2007 (FAO, 2010) to 24.7 kg per capita $y^{-1}$ in 2024 (FAO, 2024). These numbers are very significant because (i) per capita consumption in Asia is now 11% higher than in Europe, reflecting the increase in Asian per capita GDP; and (ii) Due to the combination of population ratio (Asia : Europe = 6.5) and per capita consumption difference, Asia annually consumes 119 Mt of aquatic products and Europe consumes only 16 Mt. This huge and widening gap, allied to the fact that 90% of aquaculture production occurs in Asia, means that Europe and North America face a critical problem with respect to the supply of aquatic products—and therefore food security for the coming generations.

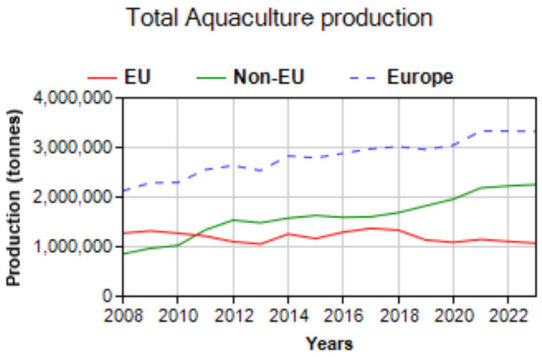

*Fig. 1. European aquaculture production over the last two decades. Growth in the EU has been negative.*

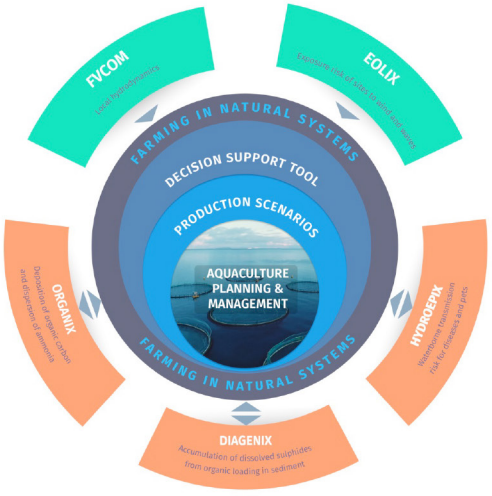

*Fig. 2. FINS framework for aquaculture sustainability and growth.*

Whereas in Asia, freshwater aquaculture in ponds and lakes makes up 70% of production, in the West, cultivation is mainly in coastal bays and estuaries. This means that Marine Spatial Planning (MSP) plays a key role in harmonising multiple uses through appropriate allocation of space (Strand et al, 2025) but MSP determines the effect of the environment on aquaculture—imposing constraints on where the activity can occur; MSP does not address the effect of aquaculture on the environment: other types of mathematical models are required to address this (Ferreira, 2025).

*(Continued on next page)*

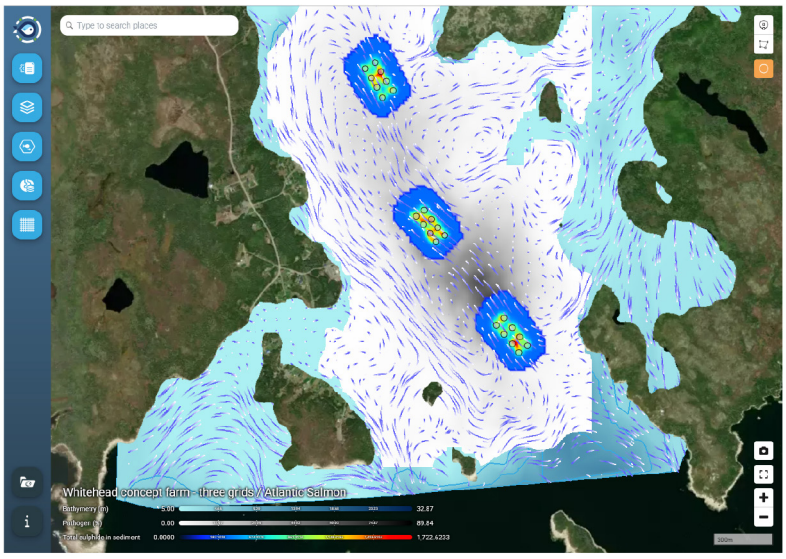

*Fig. 3. FINS results for Whitehead Harbour, Nova Scotia, showing 3 salmon grids, bathymetry (light blue) and velocity fields, sulphide in the sediment (blue-red scale), and pathogen emission from the southernmost grid (greyscale).*

These models are extensively published in the literature and have been applied in various parts of the world, but there is a need for frameworks that bring together complex models to deal with issues such as sediment organic enrichment and pathogen outbreaks, that occur at very different time and space scales.

**Methods**

The FINS (Farming In Natural Systems) framework (Fig. 2) combines a set of models that address specific issues related to finfish and shellfish aquaculture.

These include near-field deposition and fate (diagenesis) of particulate organics, far-field nutrient enrichment, using ammonia as an indicator, together with oxygen reduction, and for bivalves, chlorophyll (as a proxy for food) depletion. Detailed models for water circulation are the base for understanding the distribution of key performance indicators (KPI) of aquaculture sustainability.Associated with these circulation models are well-tested physiological models for growth of finfish and shellfish species such as salmon, bass, bream, oysters, and mussels. FINS is fully georeferenced and can represent multiple types of aquaculture structures within a bay, including cages, cage grids, rafts, and longlines—the location, type, and dimensions of structures are user-defined.

**Results and Discussion**

The results presented in this paper illustrate the outputs of FINS for different KPI in selected bays in Nova Scotia, Canada. Fig. 3 shows four (concept) layers for Whitehead Harbour, Nova Scotia: the bathymetry and residual velocity (from the FVCOM model) for the entire bay and three user-defined grids of eight 30 m diameter salmon cages; outputs of three models (circulation, diagenesis, and pathogen emission) show the effects of salmon cultivation through a 500-day cycle.

The near-field deposition of particulate organics from uneaten and waste feed is simulated, together with the consequences for sediment diagenesis, in this case for sediment sulphide concentration; far-field dispersal of a pathogen emitted from the southernmost grid is also shown—the residual currents transport the pathogen NW leading to infection in the central and northern grids. This allows managers to examine the interaction between existing or potential farms with respect to disease connectivity, promoting improved animal welfare, natural biodiversity, and ecosystem sustainability.

FINS allows for models external to the application to be displayed, including GeoJSON outputs from Geographical Information Systems. This helps to take spatial planning to the next level. By applying different mathematical models to aquaculture structures placed in suitable areas and examining e.g. the potential effect of pathogen dispersal or eutrophication in adjacent zones, MSP can be leveraged to account for the dynamic nature of coastal ecosystems.

*(Continued on next page)*

FINS also represents a major technological advance in a platform of this type when compared to conventional desktop solutions. FINS runs in the browser, like any website, and users can access and use it anywhere, from any computer or tablet—even on TV. In a world that increasingly relies on the Internet of Things (IoT), this is a critical advantage. The option to use the GPU for the graphics primitives in FINS, including design of any type of polygon as an aquaculture structure, animation of residual current flows, and various other features, has led to very significant improvements in speed and functionality.

**Acknowledgements**

The authors wish to acknowledge funding from the Atlantic Fisheries Fund, Canada and the Horizon Europe NovaFoodies project. We also owe a profound debt of gratitude to the late Prof. Jon Grant, a huge enthusiast of the FINS project.

[+]Corresponding author, joao@hoomi.com

## Introduction

Aquatic food security is increasingly dependent on farming and accounts for over 57% of all finfish and shellfish consumed worldwide (FAO, 2024). The overwhelming majority of aquaculture takes place in emerging economies (88% of the 131 X $10^6$ t annual production[1] in 2022 (FAO, 2024)), which are largely responsible for the consistent 6-8% annual increase in production. This growth rate, fuelled by the twin pressures of human population expansion and the need to increase per capita consumption of fish, and stimulated by the stagnation or decrease in wild capture for key species, is a clear environmental and social pressure (Costello et al, 2020).

To ensure the sustainable growth of aquaculture, given limited resources such as space and water quality and the need to balance competing uses and equilibrium of ecological, economic, and social factors, it is essential to determine carrying capacity (CC) in an integrated manner (Inglis et al, 2000). CC is presently defined through four pillars: physical, production, ecological, and social (Ferreira et al, 2013; Sanchez-Jerez et al, 2016). Together, these correspond to the FAO definition of the Ecosystem Approach to Aquaculture (EAA), predicated on optimisation and preservation of human capital, ecosystem services, and multiple system uses (Soto et al, 2008).

Although these pillars are accepted as the basis for quantifying sustainable carrying capacity, and different approaches have been proposed to evaluate each component, the pillars need to be combined into a single recommendation to policymakers to provide a number or range for stocking a particular area with cultivated species. To address this need, the Aquaculture Rating Thresholds for Ecosustainability (AQRATE) framework was developed, which brings together the physical, production, ecological, and social pillars of carrying capacity in order to provide a precautionary estimate of where, what, and how much can be cultivated in a given area (Ferreira, 2025). The focus is on open water bodies (inshore or offshore, marine or freshwater), since these present the greatest challenges with respect to connectivity, competing uses, and ecological balance, but a subset of this approach could be applied to pond-based systems.

1

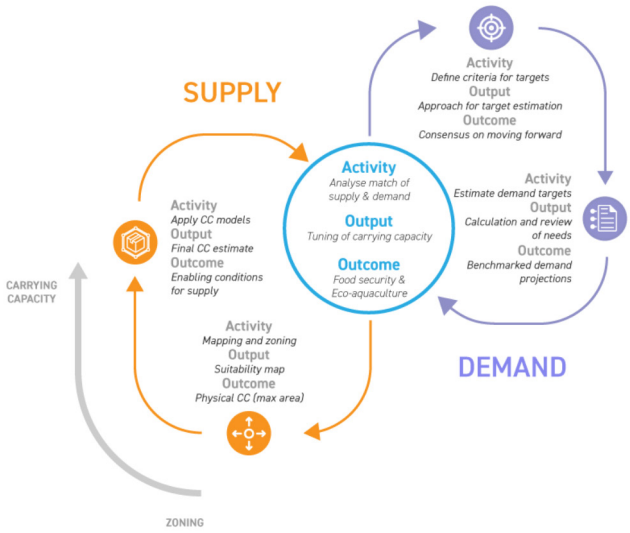

*Fig. 1. General approach to integrated CC assessment.*

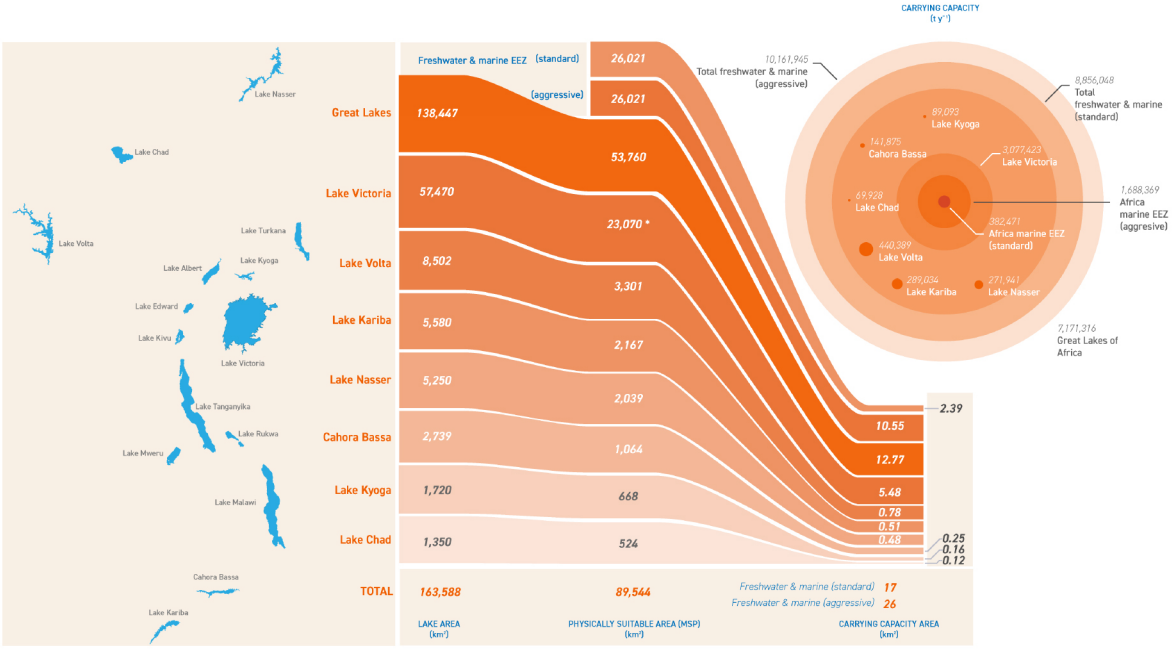
*(Continued on next page)*



*Suitable inshore area: 3,224 km$^2$; suitable offshore area: 19,846 km$^2$. Total suitable area calculated bottom-up from MSP, all others calculated top-down using the proportion of total area of the system(s).

*Fig. 2. Carrying capacity of the great lakes of Africa and the African marine Exclusive Economic Zones.*

The aims of this work were to:

1. Develop a methodology to integrate different aspects of aquaculture carrying capacity to determine an overall range of areal occupation and stocking density that can be used for management;
2. Test the integrated framework in different ecosystems to make real-world predictions and assess the comparative role of each pillar;
3. Provide policymakers and managers with a framework that is simple to use and only moderately data-intensive, to meet the needs of aquaculture development in different parts of the world.

**Approach**

The general approach used for estimation of carrying capacity is shown in **Error! Reference source not found.**. The supply-side steps (left), address both the MSP process and the determination of carrying capacity. The final value or range for CC corresponds to what can be produced in a sustainable manner. In many parts of the world, inshore aquaculture is prevalent, so the AQRATE framework deals with both inshore and offshore conditions[2].

The main emphasis of this paper is on the development of the framework and therefore the focus is on environmental and social carrying capacity. However, it is important from a policy perspective to understand the potential demand for what can be supplied, to avoid creating unrealistic expectations that can result in negative social and economic consequences.

The output of Marine Spatial Planning (MSP) is the zoning of a particular water body, using a classification scheme normally based on Multi-Criteria Evaluation (MCE) implemented by means of a Geographic Information System (GIS). This broadly corresponds to the physical carrying capacity pillar. MSP yields a set of areas $A_m$ (one per zone) corresponding to the zoning of the water body of interest. To each area $A_m$ is associated a suitability class; therefore, although the sum of zone areas equals the area of the water body, the sum of suitable zone areas will almost always be less than the water body area. For any suitable zone, given the available area $A_m$ determined by MSP, the next step is to determine a precautionary coefficient to be applied, resulting in a new, smaller area $A_{cc}$ that is available for cultivation taking into account the production, ecological, and social pillars.

The precautionary factor a is determined heuristically, taking into account a number of key factors (Eq. 1).

*(Continued on next page)*

Where:
$a_r$ = production-based maximization of harvestable biomass (Bacher et al., 1998; Smaal et al., 1998; Inglis et al, 2000), or profit (Ferreira et al, 2007)
$a_e$ = eutrophication potential based on overall dissolved emissions from an area
$a_d$ = pathogen risk and connectivity
$a_s$ = acceptable social impact of structures

Simple zone-scale models are used to quantify the various components of a, including (i) a model for space allocation constraints, such as typical grid layouts and spacing, how many grids should makeup a typical farm, and how far apart farms should be spaced; (ii) a mass balance model for emissions of dissolved nutrients, allowing water quality thresholds to be tested in order to optimise aquaculture stocking density; and (iii) a pathogen model addressing stocking density, connectivity, and risk, which provides information on both stocking density and spatial distribution within an (MSP) suitable area. The final value or range for CC for each zone is determined through a stepwise procedure whereby the lowest estimate for CC is taken to be the recommended value, based on the results obtained from the physical, production, ecological, and social pillars. This assessment must be carried out zone by zone, because the limiting factor can vary among zones (e.g. in some zones eutrophication may limit CC, in others social CC or disease risk may be limiting) and a bulk approach can more than double the estimate of CC, particularly when a simulation considers offshore areas with larger cages and inshore areas with artisanal grids of small cages.

This is compared with the predicted *additional* demand, calculated by comparing current consumption with a policy target. Current consumption already accounts for the mass balance of fisheries and aquaculture and of imports and exports. The comparison between supply and demand can be used to determine how aggressively some of the parameters in AQRATE can be adjusted, e.g. accepting a higher degree of eutrophication or pathogen risk as a trade-off for increasing carrying capacity.

**Results and Discussion**
Two case studies illustrate the application of AQRATE under different conditions. The Kenyan part of Lake Victoria was used for Nile tilapia (*Oreochromis niloticus*) in freshwater, and the offshore coastal area of Pakistan was used to analyse CC for barramundi (*Lates calcarifer*). The approach was then used to estimate the carrying capacity for the whole of Africa. Due to space limitations, only a summary of the results for Kenya and the wider application to Africa are shown herein.

The current population of Kenya is 53.8 million. The estimated CC would be 258,279 t y-1 live weight with the data used in this case study, yielding 180,795 t y-1 of tilapia fillet after deducting 30% for offcuts such as head, bones, and frame, which would add 3.4 kg fish consumption per capita per year. An alternative calculation, based on increasing the current consumption of 5 kg fish ind-1 y-1 by 10 kg, would meet this target for about 18 million people, i.e. 30% of the present population. Based on current market prices, the annual gross income corresponding to the carrying capacity estimated with AQRATE would be about 270 million USD.

The carrying capacity for all of Africa, determined by scaling the freshwater and marine case studies used in AQRATE, is shown in Fig. 2. Overall, the projection for sustainable aquaculture production in Africa is between 8.8 and 10.2 million tonnes per year, bearing in mind that only a subset of the freshwater area was used.

This compares well with estimates of 11 million tonnes in 2030 in the HIGH scenario calculated using the IMPACT model (Chan et al, 2021), particularly considering that the AQRATE estimate does not include land-based ponds—Egypt alone produces around 1.6 million tonnes annually (FAO, 2024), of which 86% is pond culture.

# CULTIVATION OF *Tetraselmis chui* AS A VALORISATION PROCESS FOR LIQUID SIDE STREAMS FROM SEAFOOD AND MEAT PROCESSING

M. Ferreira*, P. Frade, P. Iglesias

ANFACO-CYTMA, Department of Marine Resources and Aquaculture
Colexio Universitario 16, 3630 Vigo, Spain
E-mail: martina@anfaco.es

## Introduction

Microalgae are highly valuable as a source of biomass for a range of applications, from food and feed to cosmetic ingredients or biofertilisers. Moreover, they have a great potential as bioremediating organisms for wastewater from different sources due to their capacity to remove inorganic nutrients, thus mitigating environmental impacts derived from discharge or depuration costs.

The valorisation of liquid side streams through microalgae cultivation is one of the activities of IMPRESS (Innovative approaches for marine and freshwater-based ingredients to develop sustainable foods and value chains), a Horizon Europe project aimed at the co-creation, development and promotion of new and improved products and processes based on low-trophic aquatic species, both wild and farmed.

## Materials and methods

Three different liquid side streams -cooking water from octopus and tuna processing and brine from serrano ham maturation- were used to culture *Tetraselmis chui*. All three side streams contained different concentrations of inorganic nitrogen (ammonium, nitrite and nitrate) and phosphate. Tuna cooking water was rich both in nitrate and ammonium, whereas octopus cooking water and brine contained ammonium and traces of nitrate and nitrite. N:P ratio varied between 2 and 108 (Table 1). Octopus and tuna cooking were previously subjected to centrifugation to remove solid particles and oil and to membrane nanofiltration to remove protein; all these fractions are valuable for valorisation. Brine was mesh-filtered to remove large particles.

Non-axenic *T. chui* was cultured in 1-l flasks in triplicate, in the following culture media: 1) control cultures were grown in seawater supplemented with commercial nutrients by Aqualgae S.L. (Goldmedium A: 2 mM $NO_3^-$, 0.2 mM $PO_4^{3-}$ and Goldmedium B: micronutrient premix; 2) liquid side stream + Goldmedium B; 3) 50% liquid side stream + 50 % seawater + Goldmedium B. Flasks were aerated and exposed to 14 h: 10 h light:dark cycles. When necessary, NaCl was added to culture medium to provide salinity levels appropriate for *T. chui*.

Cell counts were done regularly along the culture cycle. Cultures were kept for 9-11 days, until the onset of stationary phase in control flasks. At that time, the content of the flasks was centrifuged to remove cells and culture medium was analysed to determine its microbiological and physico-chemical features.

## Results

Control, seawater cultures reached highest cell densities at the end of the growth phase. Cultures kept on 50 % liquid side stream + 50 % seawater reached similar values to control cultures, except for *T. chui* cultured in tuna cooking water. On the contrary, *T. chui* kept in pure liquid side streams did not grow, and cell densities remained constant from inoculation (Table 2).

Spent culture media showed different microbiological quality. Initial liquid side streams contained mesophilic aerobic microorganisms and Enterobacteria (Table 1). After the cultivation cycle, the content of both groups of microorganisms strongly increased in the cultures with 50 % or 100 % octopus or tuna cooking water; nevertheless, culture medium consisting in 50 % or 100 % serrano ham brine showed lower bacterial counts than the initial brine (Table 2).

## Discussion

The concentrations of inorganic N and P in the liquid side streams were enough to sustain *T. chui* growth when used at a 50 % concentration. In cultures carried out in pure side streams, turbidity caused by the rapid bacterial proliferation in seafood cooking water or due to fine particles in the case of brine could decrease light availability inside the flasks.

*(Continued on next page)*

Table 1. Content of inorganic nitrogen and phosphate and bacterial counts in liquid side streams used for the culture of *T. chui*.

| | Tuna cooking water | Octopus cooking water | Brine from serrano ham |
|---|---|---|---|
| $NO_3^-$ (mM) | 1.95 | 0.01 | 0.02 |
| $NO_2^-$ (mM) | 0.02 | 0.00 | 0.00 |
| $NH_4^+$ (mM) | 15.29 | 9.71 | 7.53 |
| $PO_4^{3-}$ (mM) | 0.55 | 4.70 | 0.07 |
| N:P | 31.30 | 2.07 | 107.80 |
| Mesophilic aerobic microorganisms (cfu $ml^{-1}$) | 18,000 | 90,000 | 1,200,000 |
| Enterobacteria (cfu $ml^{-1}$) | 1,000 | 1,600 | 3,000 |

Table 2. *T. chui* cell density and bacterial counts in different culture media.

| Liquid side stream | *T. chui* culture medium | Cell density ($10^6$ cells $ml^{-1}$) ± s.d. | Mesophilic aerobic microorganisms (cfu $ml^{-1}$) | Enterobacteria (cfu $ml^{-1}$) |
|---|---|---|---|---|
| Tuna cooking water | Control | 4,59 ± 0,81 | <10 | <10 |
| | 50 % | 1,90 ± 0,62 | $2.8\ 10^6$ | <10 |
| | 100 % | 0,57 ± 0,20 | $1.5\ 10^6$ | <10 |
| Octopus cooking water | Control | 5,58 ± 0,29 | $1.4\ 10^3$ | <10 |
| | 50 % | 4,20 ± 0,10 | $6.95\ 10^5$ | $1.4\ 10^4$ |
| | 100 % | 0,61 ± 0,09 | $2.7\ 10^7$ | $1.5\ 10^5$ |
| Serrano ham brine | Control | 6,21 ± 0,33 | $3.4\ 10^4$ | <10 |
| | 50 % | 5,93 ± 0,08 | $1.1\ 10^4$ | <10 |
| | 100 % | 0,66 ± 0,11 | $2.0\ 10^4$ | <10 |

Bacterial growth in both types of seafood cooking water was probably due to the content of organic carbon. Organic carbon in brine was lower, and the growth of *T. chui* prevented bacterial proliferation.

In order to use these types of liquid side streams as culture medium for microalgae, a pretreatment, e.g. pasteurisation, must be applied to prevent bacterial proliferation.

## Introduction

The rapid expansion of invasive species within marine ecosystems poses significant ecological and economic threats, frequently resulting in the displacement of native biodiversity and the destabilization of coastal environments (Mancinelli et al., 2021). However, these ecological challenges also present an opportunity: invasive species may serve as valuable, yet underutilized, biological resources. In aquaculture, their use as alternative protein sources presents a promising, sustainable solution to reduce dependence on conventional feed ingredients and support circular economy.

Along the Italian coastline, several alien species have been identified, with potential for valorization, notably:

- Whole Blue Crab (Callinectes sapidus) (a in Fig.1) – A highly invasive species in Italy, whose growing biomass is difficult to valorize. Most of its population, particularly females and smaller individuals, is currently discarded or destroyed (Azzurro et al., 2024).
- Soft Tissue from Bivalve (Anadara sp., Arc clam) (b in Fig.1) – An invasive mollusk species along the Adriatic coast with limited commercial use and low market value (Morello et al., 2004).

This study investigates the potential of incorporating these invasive species into the diet of juvenile seabass (Dicentrarchus labrax), aiming to turn an environmental liability into a sustainable asset for Mediterranean aquaculture.

## Materials and Methods

This trial was conducted at the Laboratory of Aquaculture, Department of Veterinary Medical Sciences, University of Bologna (Cesenatico, Italy). Juvenile seabass (Dicentrarchus labrax; initial average weight 5 ± 2 g) were sourced from Panittica Italia and acclimated for two weeks. Fish (n= 100/tank) were randomly stocked into nine 450 L square tanks (three replicates per dietary treatment) and reared for ~30 days. Tanks operated within a closed recirculating aquaculture system (RAS) equipped with mechanical sand filtration, ultraviolet lights, and a biofiltration as described by Parma et al. (2023). Water parameters were maintained at 24 ± 1.0 °C, 25 ± 5.0 g/L salinity and oxygen levels at 8.0 ± 1.0 mg/L using a liquid oxygen system. Fish were fed pelleted isoproteic and isolipidic diets, containing varying levels of Anadara soft tissue meal (AM) and whole blue crab meal (BCM): 0% (control), 5% AM + 5% BCM (diet A), 5% AM + 10% BCM (diet B). Feeding was performed to satiation with a 10% surplus twice daily (8:30 and 16:30) six days per week.

**Figure 1:** Specimen of *a*) *Callinectes sapidus; b*) *Anadara* sp., Arc clam.

*(Continued on next page)*

At the beginning and end of the experiment, all fish are anesthetized or euthanized with tricaine methanesulfonate (MS-222). Growth performance and whole-body and dietary proximate analyses parameters are calculated. Gene expression related to digestion (amyl, lip and pept), appetite (pomc a, ghrl, cart), growth (gh, igf1, oxidative stress (sod and cat) and physiological stress (hsp70 and hsp90) are analyzed to evaluate the nutritional and physiological response to the different diets. All experimental procedures were approved by the Ethical Scientific Committee for Animal Experimentation of the University of Bologna (ID 113/2020-PR), following European Directive 2010/63/EU.

Results and Discussion

Preliminary results suggest that the inclusion of blue crab meal and Anadara meal could positively influence the growth performance and feed intake of juvenile seabass. Blue crab meal, with its high protein percentage (> 40%) and abundance of essential fatty acids and minerals (Arena et al., 2024), may promote enhanced growth rates, although its high chitin content from the carapace could pose digestibility challenges if not properly managed. Anadara meal, known to be a fish attractant could increase the ingestion rate, while its high hemoglobin-derived iron content may contribute to improved oxygen transport, enzymatic activity and immune support in fish. Nevertheless, potential risks such as heavy metal accumulation in Anadara tissues highlight the need for careful sourcing and balanced formulation (Solang et al.,2021).

Conclusion

These preliminary findings support the broader concept of utilizing invasive species to reduce dependence on conventional fishmeal, fostering a more sustainable and circular aquaculture system.

**Introduction**

Organic aquaculture is among the most demanding food production sectors in Europe, as it must adhere to the core principles of health, ecology and fairness, ensuring sustainable practices that protect animal welfare, ecosystem integrity, and social equity (European Climate, Infrastructure and Environment Executive Agency). In 2020, total organic aquaculture production in the EU reached 74,000 tonnes, accounting for 6.4% of total EU aquaculture. Within this, European sea bass (*Dicentrarchus labrax*) and gilthead seabream (*Sparus aurata*) contributed 2,750 tonnes, representing just 1.5% of the total production for these two species (Estévez & Vasilaki, 2023).

The sector is expected to grow, driven by increasing consumer demand for organic seafood. However, feed-related constraints hinder expansion: certified organic feed ingredients, especially fishmeal from trimmings, are limited, and synthetic amino acids are banned. Despite promising results with organic diets, their heavy reliance on fishmeal often makes them economically unviable. In this context, animal land-based protein sources have shown encouraging outcomes across multiple species (Galkanda-Arachchige et al., 2020). Additionally, single-cell proteins (SCP) are emerging as promising candidates for integration into feed formulations, potentially improving both sustainability and cost-effectiveness (Oliva-Teles & Gonçalves, 2001; Marchi et al., 2023). This study evaluates a novel, cost-effective organic diet for gilthead seabream, compared to both a conventional commercial and a commercial organic diet. The experimental diet is designed to match the lower fishmeal inclusion typical of conventional feeds by reducing the higher fishmeal levels commonly found in organic diets. This is achieved through partial replacement with yeast extract and certified organic poultry meal, aiming to improve economic sustainability while remaining compliant with organic standards.

**Materials and Methods**

This trial will be conducted at the Laboratory of Aquaculture, Department of Veterinary Medical Sciences, University of Bologna (Cesenatico, Italy). Gilthead seabream (S*parus aurata* ~120 g) from two genetic lines (fast-growing and standard), (n= 30/tank) will be randomly stocked into eighteen 800 L square tanks (three replicates per dietary treatment and genetic line) and reared for ~3–4 months until reaching ~320 g. Tanks will operate in a recirculating aquaculture system (RAS) with mechanical and biological filtration and UV treatment. Water parameters will be maintained at 24 ± 1 °C, 30 ± 3 g/L salinity, and 8.0 ± 1.0 mg/L $O_2$. Three isoproteic (43%) and isolipidic (17%) diets will be tested: a conventional, a commercial organic, and a novel organic diet. Fish will be fed to satiation with a 10% surplus twice daily, six days per week. All fish will be PIT-tagged and measured for weight and length at the start and end of the trial. Growth performance (SGR, FI, FCR) will be evaluated at the tank level. Feed and carcass composition will be analyzed at the beginning and end; fillet composition, texture, colour, fatty acid profile (via HPLC), and nutrient utilization will be evaluated on 10 fish per group and diet. Blood from the same fish will be collected for plasma biochemical analysis.

*(Continued on next page)*

**Results and Discussion**

The novel organic diet for gilthead seabream is expected to match the growth performance of the commercial organic diet while approaching the cost-effectiveness of conventional feed. With reduced fishmeal content, partly replaced by certified organic poultry meal and yeast extract, feed conversion ratio should remain optimal and specific growth rate similar across treatments. Economic sustainability is anticipated to improve by lowering dependence on costly organic fishmeal, while maintaining compliance with EU organic standards. Fillet quality (composition, texture, colour, fatty acids) should remain within acceptable organic ranges, with only minor lipid class changes from protein source differences. Plasma biochemical values are expected to stay within physiological limits, indicating no health issues. Overall, incorporating certified poultry meal and yeast extract could enable cost-effective organic diets that maintain growth, quality, and welfare, supporting the sustainability and expansion of EU organic aquaculture.

**Conclusion**

The novel organic diet, incorporating certified poultry meal and yeast extract to partly replace fishmeal, is expected to sustain growth, fillet quality, and fish health comparable to commercial organic feed, while lowering costs and promoting sustainable seabream production.

**Introduction**

Microplastic pollution in marine ecosystems has become a global issue with adverse effects on biodiversity and aquaculture. They pose a physical threat to marine organisms and can act as vectors for contaminants, amplifying their impact on the food chain. Oysters are filter-feeding organism, thus particularly vulnerable to microplastics (MPs) and associated contaminants, resulting in a food safety risk.

This study aims to elucidate whether the Pacific oyster (*Magallana gigas*), one of the most important species in mollusc aquaculture worldwide,) act as a vector of microplastics transfer to the food chain (and what would be the role of the presence of hydrocarbons adsorbed on them in this transfer) and ii) what would be their behavior in the event of a possible oil spill in the water.

**Material and methods**

Individuals of *Magallana gigas* (approximately 10,06 - 13,22 cm from hinge to shell margin) were obtained from the Jose Mº Daporta Leiro e Hijos S.L. enterprise, located in Ria de Arousa, Galicia, Spain. They were maintained in 4L glass aquaria with natural seawater (temperature: 17-20ºC and salinity: 37-37.5 ppt), under constant aeration and a water renewal rate of 1L day-1. They were fed daily with *ReefPulse* from Ocean Nutrition. Oysters were acclimated to the tanks and laboratory conditions for 7 days before being used in experiments.

Contaminated and uncontaminated MPs were administered to each oyster with tweezers, and their percentage of ingestion and retention time were evaluated. The microplastics used were green, pink, and black Gütermann polyester fibres, 2 mm in length. Contamination with diesel was performed as follows. MPs were mixed with 50 ml of 100% diesel at 150 rpm for 72 hours and then washed with seawater at 170 rpm for 28 hours to remove excess non-adsorbed diesel. Uncontaminated MPs were prepared following the same procedure using seawater instead of the diesel solution.

Individual oysters were submersed in a diesel-seawater mixture (ratio 1:1000) for 24 hours. Their filtering activity (time with their valves open) was evaluated by observing them for 10-minute cycles during 5 days (including the 24-hour exposition).

**Results and discussion**

Oysters ingested 92% of the polyester fibres supplied, with an average of around 4,9 particles per individual and 0.2 particles per gram of wet tissue, without showing a statistically significant colour influence. The presence of hydrocarbons did not affect their palatability, but microplastics with adsorbed diesel were retained significantly longer (6 h of average) before being expelled, with a maximum retention of 24h, while uncontaminated ones had a mean of 21 min. Additionally, an increased filtration activity was observed in oysters exposed to diesel, raising questions about the physiological impact of contaminants on oysters as well as their ability to adapt to polluted environments.

*(Continued on next page)*

**Conclusions**

Aquaculture is a key activity to food supply and economic development, thus understanding the interaction between farmed organisms and emerging contaminants is essential for designing mitigation strategies and ensuring the viability of this activity in future. This study provides relevant information on the interaction between oysters, microplastics, and diesel pollution, with implications for aquaculture. According to the results, oysters can be considered a vector for transferring microplastics into the food chain. Furthermore, the time window in which microplastics would be available for transfer to a predator depends on the substances absorbed in them, highlighting the ability of microplastics to act as carriers of other contaminants. It has also been shown that oysters are sensitive to the presence of diesel in the water, changing their behavior significantly (p-value = 0,0000364). Further experiments should be conducted to determine what implications this might have for their commercialization for human consumption.

# THE DELICATE BALANCE BETWEEN IRON DEFICENCY AND EXCESS IN AQUATIC SPECIES: A SHORT REVIEW

Claudia Figueiredo-Silva

Eden Prairie, MN 55344
United States
*csilva@zinpro.com

*Introduction: Essentiality of Iron (Fe)*

By playing an essential role in the activation and modulation of several processes involved in immune response, optimal trace mineral nutrition is central in helping fight stress and disease in the increasingly challenging production conditions of farmed aquatic animals. Iron is a trace mineral of fundamental importance to the health and performance of farmed aquatic species. It is required for several biochemical processes, including electron transfer reactions, gene regulation, the binding and transport of oxygen, and regulation of cell growth and differentiation. Our presentation aims to explore the essential roles of Fe in fish, focusing on its impact on hemoglobin synthesis and mitigation of anemia, immune cell functionality, stress resilience, and the delicate balance between deficiency and excess. Recommendations on dietary Fe supplementation strategies will be drawn from this short review of published literature.

*Primary Signs and Causes of Fe Deficiency*

Iron deficiency can impair immune response, making fish more susceptible to infection and environmental stressors. Deficiency primarily manifests as hypochromic microcytic anemia, which is characterized by reduced hemoglobin, hematocrit, mean corpuscular volume, and mean corpuscular hemoglobin. This condition leads to decreased growth rates, reduced appetite, lower feed efficiency, and poor overall performance. Characteristic hypochromic microcytic anemia has been detected in various fish species, including brook trout, rainbow trout, Atlantic salmon, red sea bream, yellowtail, eel, and carp fed low-Fe diets. In catfish, Fe deficiency suppressed hematocrit, hemoglobin, and plasma Fe levels, and caused transferrin saturation. Although gills play an important role in Fe acquisition, particularly in developing fish where the digestive tract is not fully functional, the gastrointestinal tract is considered the major site of Fe absorption. Replacement of fish meal with alternative ingredients lower in Fe content and bioavailability requires proper Fe balancing to avoid nutritional deficiency and the associated negative impacts on performance and health of fish.

*Non-Nutritional Causes of Anemia*

Anemia in fish can also be caused by infection and infestation. Viral and bacterial infections, such as infectious salmon anemia virus (ISAV) and *Aeromonas hydrophila,* can cause anemia. Parasites, such as *Argulus sp.* and *Trypanosoma sp.* contribute to anemia through blood loss and hemoglobin digestion. Parasitic infections are a growing concern in mariculture. More specifically, monogeneans are among the most threatening ectoparasites in aquaculture due to their impact on economically relevant finfish species, including gilthead seabream. Sparicotylosis, caused by *Sparicotyle chrysophrii*, leads to severe anemia and histopathological lesions in the gills, and represents the number one health concern in gilthead seabream production units under offshore farming conditions across the Mediterranean Sea. We will explore how optimization of Fe supplementation may help mitigate the impact of these infections and infestations, which seem to have become more common and severe with current observed climate changes.

*Current Iron Requirements of Fish*

The Fe requirements of fish vary, depending on species, age, and physiological conditions. Revised by Lall and Kaushik (2021), and Prabhu *et al*., (2004), the minimal dietary inclusion level of Fe is influenced by factors such as the type of experimental diet used, dietary interactions, and the mineral concentration of water. Hemoglobin levels are considered appropriate criteria for determining Fe requirements. For example, Atlantic salmon requires Fe levels that support hemoglobin regeneration and overall health, with bioavailability varying significantly among different Fe sources. Research indicates that ferrous sulfate and ferric chloride have similar bioavailability, while Fe from blood meal and Fe-hydroxy methionine analogues show higher bioavailability. In Nile tilapia, Fe-amino acid complex showed to be a better source than inorganic Fe to improve performance, enhance hemoglobin, and reduce oxidation. Specific dietary Fe requirements for various fish species are generally in the range of 30 to 100 mg/kg of diet.

*(Continued on next page)*

*The Delicate Balance Between Fe Deficiency and Excess*

Maintaining a balance between Fe deficiency and excess is essential for optimal fish health. While Fe deficiency can impair hemoglobin synthesis and immune function, too much Fe or provided in certain forms, can promote oxidation of feed components (e.g. vitamins, fatty acids and astaxanthin), affecting fish performance, health and organoleptic properties. Ingredients such as blood meal have a high content of haem-Fe, and although of relatively good bioavailability, it may also promote oxidation of feed components. Excess Fe in chemical forms that become readily available in the gut can also promote bacterial growth and oxidative stress. Iron not efficiently absorbed may feed pathogenic bacteria, which ultimately affects fish health. A decrease in the amount of Fe available to the human gut microbiome reduced the growth of potentially pathogenic bacteria. Growth of *Escherichia coli and Salmonella typhimurium* were significantly impaired when cultured independently in Fe-deficient media. In contrast, depletion of Fe did not affect the growth of the beneficial species, *Lactobacillus rhamnosus*, when cultured independently. In Atlantic salmon, Fe overload was shown to modulate the immune response in fish and increase susceptibility to *Piscirickettsia salmonis* infection. Moreover, Fe chelated with deferoxamine (DFOA), a pharmaceutical compound used to bind Fe and aluminium, enhanced salmon survival and reduced bacterial load. This indicates that chelated Fe sources, in comparison with inorganic and elemental forms of Fe, are better at positively modulating the gut microbiome of fish. Replacement of an inorganic trace mineral premix with metal-complexed minerals showed a positive modulation of the microbiome in tilapia intestine, which may be at least partly related to the replacement of an inorganic source Fe source with a form of complexed Fe included in the premix.

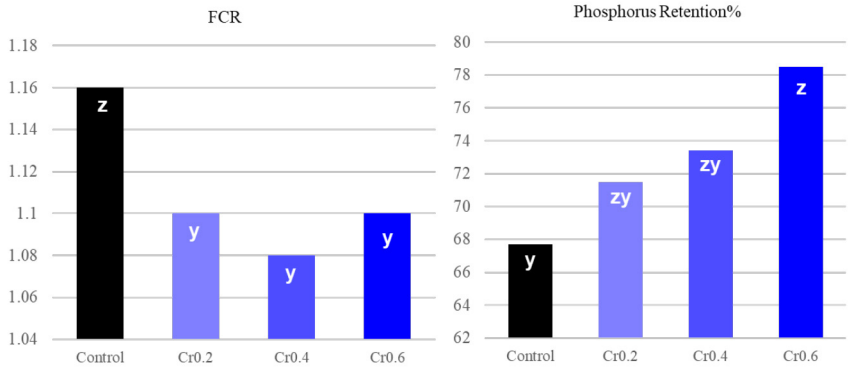
Iron is a fundamental trace mineral for fish health, playing crucial roles in oxidation-reduction activity, oxygen transport, and immune function. Maintaining a balance between dietary Fe deficiency and excess is essential for optimal fish health and performance. This presentation highlights the importance of optimizing Fe supplementation levels and sources to ensure the health and productivity of farmed aquatic species.

# CHROMIUM-METHIONINE COMPLEX IMPROVES PERFORMANCE AND RETENTION OF PROTEIN AND PHOSPHORUS IN GILTHEAD SEABREAM

Claudia Figueiredo-Silva*, Jorge Dias

*Zinpro Corporation
7500 Flying Cloud Drive, #800
Eden Prairie, MN, United States
*csilva@zinpro.com

Although carbohydrates are the cheapest dietary energy source and essential for producing high-quality pellets, elevated carbohydrate (glucose) levels can pose nutritional challenges for fish compared to land animals. Dietary supplementation with Cr methionine (Cr-Met) complex proved to be consistently effective in improving utilization of glucose and feed utilization in fish, regardless of their trophic level (from carnivorous to omnivorous species), optimum temperature (warm- to cold-water species) or salinity tolerance (seawater to freshwater). The efficacy of graded dietary levels of Cr-Met complex, in the form of Availa®Cr 1000, was recently evaluated in terms of performance and whole-body nutrient retention in gilthead seabream (*Sparus aurata*). The trial was comprised of four dietary treatments: a control diet (Control) without Cr-Met complex supplementation; and three other diets, based on the Control formulation, but supplemented with Cr-Met complex at increasing doses (0.2, 0.4 and 0.6 mg.kg$^{-1}$). Diets were isonitrogenous (crude protein, 41.8%), isolipidic (16.3%) and isoenergetic (gross energy, 21.6 MJ/kg). Quadruplicate groups of 50 gilthead seabream, with a mean initial body weight of 32.1 ± 2.1 g were fed one of the four experimental diets for 91 days. At the end of the trial, the final body weight ranged between 126.4 and 134.7 g. When compared to Control, supplementation with Cr-Met complex resulted in significant improvements for specific growth rate (SGR), feed conversion ratio (FCR), and protein efficiency ratio (PER); being highest at 0.4 mg.kg$^{-1}$. The positive effect of Cr-Met complex on seabream performance was associated with a better utilization of glucose, as indicated by the significantly lower activities of PEPCK and significantly higher activities of HK and GK in the liver of fish fed diets supplemented with the highest Cr-Met complex levels. By improving the utilization of glucose (dietary carbohydrates), Cr-Met complex spared the utilization of protein for growth purposes which turn out in 15% more protein being retained in the body. Interestingly, supplementation with Cr-Met complex has also significantly improved phosphorus retention; 16% more P retention at 0.6 mg.kg$^{-1}$. In summary, improvement of carbohydrate utilization with the supplementation of Cr-Met complex is proven to be an effective strategy to improve seabream growth, feed efficiency, N and P retention and consequently minimize nutrient excretion in aquaculture. Harnessing a unique mode of action, it represents a complementary tool to support the implementation of improved feeding strategies aiming to advance sustainability goals and profitability of aquaculture operations.



# EFFECT OF SMOLTIFICATION REGIMES ON VACCINE EFFICACY; DEMONSTRATED IN A CLINICAL STUDY WHERE ALPHA JECT MICRO 7 ILA VACCINATED A. SALMON HAVE BEEN CHALLENGED WITH ISAV

C. Elgen*, F. Finne-Fridell, R. Torrissen, M. Andersen, M. Karlsen, A. Sandtrø

*PHARMAQ part of ZOETIS
Harbitzalléen 2, Oslo
frode.finne-fridell@zoetis.com

Over the last three decades Infectious Salmon Anaemia (ISA) has periodically caused high mortality in Atlantic salmon (*Salmo salar*) aquaculture. The severity of the outbreaks in terms of mortality levels and virus detection (both virulent and low /non-virulent) has varied both within and between sites and has primarily been handled by stamping out, removing affected cages, or intensified surveillance.

PHARMAQ developed an ISA challenge model in 2002, and later demonstrated proof of concept for an ISA vaccine based on a European subtype of the virus. Vaccine efficacy was further demonstrated in evaluated challenge models (both IP and cohabitation), which contributed to the documentation of multi- (ALPHA JECT® 5-1 and ALPHA JECT ® micro 7 ISA) vaccine for salmonid markets.

The last decades there have also been an intensification of smolt production in all markets mainly caused by larger hatcheries, often with RAS technology. The combination of technologies result in off-season smolt production based on different smoltification protocols where different light regimes and smoltification feed, are among the most used. There are concerns related to suboptimal smoltification creating stress and further suppressed immunity (both specific and unspecific) and vaccine response. The current study evaluates different smoltification protocols followed by vaccination with ALPHA JECT ® micro 7 ILA and by ISAV challenge (both IP and cohabitation). The vaccine efficacy against experimental challenge and applicability combined with experiences from commercial use of our ISA vaccines will be presented, together with discussions related to best practice smoltification protocols combined with timing of vaccination.

The use of experimental animals was approved by the Norwegian Food and Safety Authority and internal ZOETIS Animal Ethics Committee.

# PREVALENCE AND RESISTANCE POTENTIAL OF *Flavobacterium columnare* AND *Flavobacterium psychrophilum* FROM AQUACULTURE IN BELGIUM

Amalia Putri Firdausi*[1], Frank Pasmans[2], Filip Boyen[2], Mathias Devreese[2], Deepti Patel[1], Annelies Declercq[1]

[2]Department of Pathobiology, Pharmacology, and Special Animals, Faculty of Veterinary Medicine, Ghent University, Salisburylaan 133, 9820 Merelbeke, Belgium
*AmaliaPutri.Firdausi@Ugent.be

This study aims to understand the distribution of *Flavobacterium columnare* and *Flavobacterium psychrophilum* as pathogens in aquaculture farms and to assess their resistance to antibiotics. These are significant bacterial pathogens in freshwater aquaculture, responsible for columnaris disease and cold-water disease (CWD). These pathogens can cause substantial losses in farmed fish populations, particularly under stress and poor environmental conditions. As part of the European Partnership on Animal Health and Walfare (EUPAHW) project, winter sampling campaign was conducted at aquaculture farms across the regions of Belgium, involving nine companies: five trout companies in Wallonia and four companies of sturgeon, mussel, oyster, trout, bulleye, burbot, pikepearch in Flanders. Samples collected included skin and gill mucus, water, and sediment. From these, 86 presumptive isolates of *F. psychrophilum* were recovered using selective media tryptone yeast extract salts agar (TYESA) with tobramycin and neomycin and 39 of *F. columnare* were recovered using modified shieh agar with tobramycin and preliminary phenotypic identification. To ensure accurate species confirmation, all isolates will undergo identification using Matrix Assisted Laser Desorption Ionization Time of Flight Mass Spectrometry (MALDITOF MS) and specific quantitative Polymerase Chain Reaction (qPCR). We are currently identifying of the bacterial isolates with MALDITOF and qPCR. We will look into antimicrobial resistance (AMR) of the two pathogens after confirmation of their exact identity by performing minimum inhibitory concentration (MIC) test.

# AUTOMATED DETECTION OF BARBED WIRE JELLYFISH IN CITIZEN SCIENCE IMAGERY

Jarl G. Flaten[*,1], Erling Devold[1], and Tone Falkenhaug[2]

SINTEF Nord[1]
Norwegian Institute for Marine Research[2]
E-mail: jarl.flaten@sintef.no

## Introduction

Barbed wire jellyfish (*Apolemia sp.*) is a marine organism that self-organizes into string-like colonies of length ranging from a few centimetres to over 30 metres. The individuals that make up a colony contain hair-like structures with stinging cells – making a colony resemble barbed wire both in look and touch. The genus is distributed in the Mediterranean, Pacific, and Atlantic seas. In recent years, it has been observed with great abundance along the Norwegian coast, both intact colonies and swarms of fragments. Such swarms have caused significant disruption of aquaculture operations and mass mortality events in salmon fish farms, resulting in economic losses.

The new appearance of barbed wire jellyfish along the Norwegian coast, and the ensuing challenges for Norwegian aquaculture, necessitate a better understanding of their distribution and abundance. However, these gelatinous zooplankton (such as Apolemia sp.) are often overlooked in Norwegian marine monitoring programs. Moreover, traditional sampling techniques are poorly suited for capturing gelatinous organisms, leading to significant knowledge gaps regarding their distribution, abundance, and seasonal dynamics across Norwegian waters. To address these challenges, the Norwegian citizen science portal "Dugnad for Havet" (DfH) [1] was launched in 2019.

Using expert-validated images from DfH, we have developed and benchmarked machine learning models which detect barbed wire jellyfish in citizen science images. We describe these models and their performance below. The best-performing model is intended for integration into DfH to automate identification of Apolemia sp. and is part of the development of an early-warning system through the JellySafe project.

*Acknowledgements:* We are grateful to Sajidah Ahmed, Marius Andersen, and Øystein Knutsen for discussions and assistance with various activities related to this text, including data cleaning, labelling, and model development. This activity was funded by the FHF through the project JellySafe (FHF/ 901941).

## Methodology

*The «Dugnad for Havet» (DfH) dataset.* The DfH project [1] by the Norwegian Institute for Marine Research invites participants to submit observations of gelatinous zooplankton. Each observation includes fields such as photograph(s) and/or video (optional), proposed species identification, geographical coordinates, date and time. Observations have been submitted by a broad range of users, including recreational divers, fishermen, as well as aquaculture personnel. Most images were captured using smartphones from the sea surface.

Between January 2019 and April 2025, there were 4080 observations of gel. zooplankton recorded. Notably, the siphonophore Apolemia sp. accounted for over 50% of the total observations, with 2068 records and approximately 1400 accompanying images collected to date. To ensure data reliability, each submitted record undergoes a manual validation process conducted by gelatinous zooplankton specialists.

Despite its many advantages, the DfH citizen science approach presents several inherent biases and challenges, including sampling bias, seasonal bias, observer bias, and a high validation workload. By developing models which automate identification, we aim to improve the efficiency of the validation process and leverage the growing volume of submitted images, focusing first on the most reported and harmful species Apolemia sp.

*Machine learning: architectures and training.* Citizen science images present challenges for object detection such as variable lighting, varying resolutions, camera settings, etc. After strict data cleaning, our Apolemia sp. dataset consisted of 350 images. To deal with small datasets, leveraging pre-trained models is a common strategy. We compare the recent state-of-the-art models YOLOv12 [2] and RF-DETR [3] on our detection task.

*(Continued on next page)*

The YOLO family, originally based on Convolutional Neural Networks (CNNs), has long dominated one-stage detection due to its efficacy and speed. While early versions primarily relied on local receptive fields, recent models (e.g., YOLOv12) increasingly incorporate attention mechanisms to capture broader context. In parallel, transformer-based detectors such as DETR and its successors (e.g., RF-DETR) fully embrace global attention, offering advantages in cluttered or complex scenes. These architectures may therefore excel in detecting complex or cluttered scenes, such as the elongated and diffuse morphologies of barbed wire jellyfish.

Both models were trained with 10-fold cross-validation and standard augmentations[1].

**Results and discussion**

The models were evaluated on their mean Average Precision (mAP) [4] scores, which is the percentage of objects correctly detected. Here, 'detect' means that the model predicts a bounding box covering a threshold of the ground truth bounding box. We use a threshold of 50% to indicate detection skill, and average across a threshold range of 50%-95% to reward more precise outlines.

Both the models YOLOv12 and RF-DETR performed well on the detection task, achieving mAP 50% scores of 94.0% and 91.4%, respectively. Their mAP 50-95% scores were essentially identical, at respectively 76.4% and 76.3%. This indicates that the YOLOv12 model was able to correctly detect more of the Apolemia sp. targets, but that the RF-DETR bounding boxes were slightly more precise.

*Future directions.* Our models are intended to reduce the validation workload of DfH and to be part of an early-warning system for harmful jellyfish blooms along the Norwegian coast. This development is ongoing through the JellySafe project [ref]. As more images become available through DfH, we also aim to include other gelatinous zooplankton.

A drawback of the bounding box models presented above is that they don't give precise quantity estimates. To address this, we are investigating pixel-wise segmentation models.

A standard mosaic dataloader was only available for YOLOv12, not RF-DETR.

# CONSUMER HEALTH BELIEFS AND ACCEPTANCE OF SALMON FED WITH CHICKEN INGREDIENTS: APPLICATION OF THE HEALTH BELIEF MODEL

F. Govaerts* and M. Heide

Nofima
Muninbakken 9
9019, Tromsø, Norway
Email: florent.govaerts@nofima.no

**Introduction:**
The salmon industry is seeking alternative protein sources to include in feed formulations. Fishmeal and soy protein, currently the primary protein sources in salmon feed, are criticized for their environmental impacts. However, finding an alternative protein source that is available in high volumes, cost-competitive, nutritionally adequate, and environmentally sustainable remains challenging. In this context, processed animal protein from chicken could represent a promising alternative. Nonetheless, consumer acceptance of integrating chicken into salmon feed remains a concern. European consumers may perceive feeding salmon with land-animal ingredients as unhealthy or unnatural. This study investigates how consumers' health beliefs about salmon fed with chicken ingredients influence their acceptance of such products. The Health Belief Model (Rosenstock, 1974) is the theoretical framework to explore these relationships (Figure 1).

**Material and methods.**
The study is based on survey data of 500 French and English consumers. Confirmatory factor analysis is used to assess the validity of the latent variables (value, belief, norm, empathy and intention). A structural equation modelling analysis with latent constructs is used to test the hypotheses.

**Results**:
We expect to validate the ability of the Health Belief model to explain consumer acceptance of salmon fed with chicken and uncover consumers' health beliefs regarding salmon fed with chicken and their effect on behaviour.

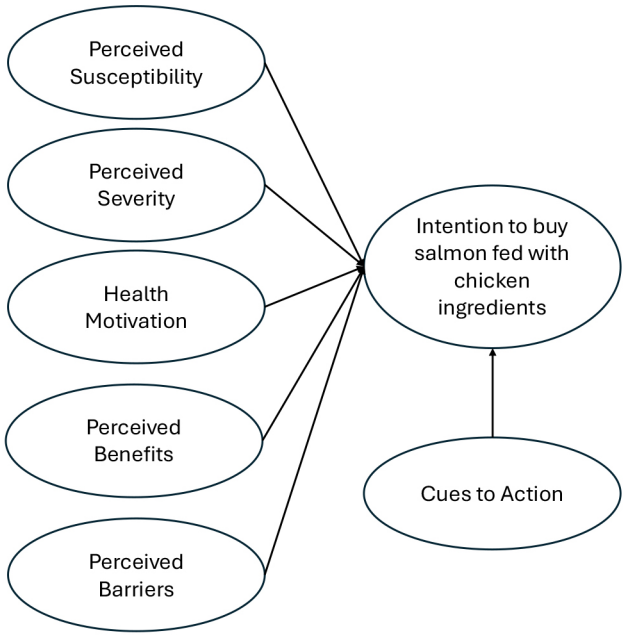

Figure 1. Health Belief Model (Rosenstock, 1974).

# DEVELOPMENT OF ANIMAL HEALTH MODELS FOR EMERGING PATHOGENS IN EUROPEAN SEA BASS (*Dicentrarchus labrax*) IN THE MEDITERRANEAN

Iria Folgueira*[1], Jose F. Cabello-Gómez[1], Daniel Páez, Iria Iglesias, María del Mar Agraso[1]

[1] Centro Tecnológico de Acuicultura de Andalucía (CTAQUA)
Muelle Comercial S/N
11500, El Puerto de Santa María
Cádiz, Spain
e-mail: fishhealth@ctaqua.es

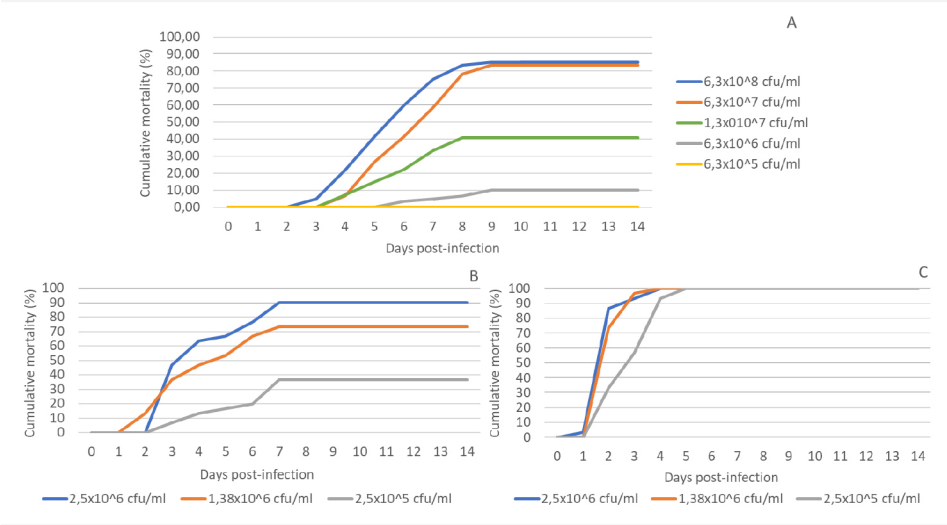
## Introduction

Bacterial diseases represent a significant issue in Mediterranean aquaculture. The number of new pathogens identified has increased over time, and one of the most common causes of the emergence of infectious diseases in marine fish is the *Aeromonas* species (Tansel Tanrikul & Dinçtürk, 2021). Over the past decade, *Aeromona veronii* has become a major problem in European sea bass (*Dicentrarchus labrax*) farming in some Mediterranean countries, with outbreaks occurring when water temperatures reach their highest values (Smyrli et al., 2019). Due to factors such as climate change, the duration of periods with higher water temperatures is increasing, which not only leads to a higher incidence of outbreaks but also allows them to persist over time. Additionally, the rise in water temperatures contributes to the proliferation of other emerging pathogens (Combe et al., 2023). Due to current restrictions on the use of chemicals or antibiotics in aquaculture production, effective and sustainable preventive treatments against systemic infections in cultured species are required (Yilmaz et al., 2022). To assess their effectiveness, the development of new standardized fish health models is necessary. In response to this challenge, we are working on the development of infection models for *A. veronii*, with plans to expand them to other emerging pathogens such as *Lactococcus garvieae*. To date, we have standardized two infection models for *A. veronii*, using intraperitoneal (IP) injection and bath immersion. These models have been tested under different conditions to evaluate their reproducibility. Preliminary results suggest that pathogenicity varies significantly with temperature, but it is also influenced by factors such as fish size, fish batch, and culture density, among others. Our next steps involve developing and validating a cohabitation infection model for *A. veronii*, as well as extending this approach to other emerging pathogens.

## Materials and methods

Bacterial isolates from internal organs of a sick fish (real outbreak in a Turkish farm) were streaked on tryptic soy agar (TSA) plates supplemented with 2% NaCl. The TSA plates were incubated at 25°C for 24-48 h and colony morphology was observed. The pure colonies were streaked again on TSA plates to determinate the specie by proteomic analyses (MALDI-TOF). Once confirmed, the *A. veronii* strain was cultured for cryopreservation and added to the CTAQUA strain collection (CT0068). A stock of different vials was generated from a liquid culture in tryptic soy broth (TSB) supplemented with 2% NaCl, with bacteria grown for 24 hours at 25 °C under agitation (150 rpm). Subsequently, bacteria were centrifuged to remove the culture medium and resuspended in a cryopreservation medium (50% glycerol in Phosphate Buffer Saline (PBS)) at a final concentration of $1\times10^9$ Colony Forming Units (CFU)/mL. Vials were stored at -80 °C. After an initial virulence test in which 10 European sea bass were inoculated by IP injection to confirm that the strain caused mortality, dose-response trials were conducted. Infection by IP injection was carried out by inoculating 0.1 ml of bacterial suspension per fish. This suspension was prepared by diluting a cryovial with an initial concentration of $1\times10^9$ CFU/mL in PBS to obtain the concentrations to be tested. Bath infection was carried out by scaling up the culture in TSB supplemented with 2% NaCl at 25°C under agitation (150 rpm) from one of the cryovials (1 mL) until obtaining a sufficient amount of culture at a concentration of $1\times10^9$ CFU/mL to prepare the dilutions to be tested in 10-liter buckets with seawater. Then, fish (20 gr) were placed in the buckets for 1 hour with aeration. The handling of the animals was performed under deep anesthesia induced by an anesthetic (benzocaine). In all the tests conducted, a control group was included, in which the fish were handled in the same way as the experimental fish but without exposure to the pathogen. Control fish were inoculated with PBS in the case of IP injection or placed only in seawater in the bucket for bath immersion. All concentrations were validated in triplicate (10 fish/tank) and after pathogen exposure, the fish were transferred to tanks in a Recirculating Aquaculture System (RAS), where all culture parameters were monitored throughout the trial. IP injection tests were carried out at 22°C, while the bath tests were conducted at 22°C and 25°C to evaluate the dose-response at different temperatures.

*(Continued on next page)*



Graph 1. Mortality curves for: A) IP injection at 22 °C, B) bath at 22 °C and C) bath at 25°C.

## Results

Graph 1 shows the cumulative mortality results for the different bacterial concentrations of *A. veronii* according to the tested route of administration and temperature.

In sight of the results, it can be concluded that there is a good dose-response relationship for the CT0068 isolate when administered to pre-ongrowing sea bass both by IP injection and by bath, making these models suitable for validating preventive strategies and treatments against *A. veronii*.

E-mail: elisa.fonsatti@unipd.it

## Introduction

The sustainability and environmental effect of conventional feed ingredients is a growing concern in aquaculture. In order to increase aquaculture sustainability, alternative protein sources are being studied. In a previous study, conducted on the same gilthead seabream (*Sparus aurata*) broodstock involved in the present analysis, no stress responses were detected following six months of feeding with diets incorporating insect and algal meals. To further characterize the effects of these alternative protein sources, we evaluated intestinal and splenic histological parameters in the same experimental population.

## Materials and Methods

In this study, three experimental diets were investigated: a control diet (CTRL) composed with conventional protein sources, and two novel diets containing a mix of four alternative protein meals, in detail *Hermetia illucens larvae, Lemna minor, Nannochloropsis gaditana*, and *Alaria esculenta* at 5% (L1) or 10% (H1) inclusion levels. For six months Gilthead seabream broodstock (n=66, equally divided in three groups) were fed with the three experimental diets. Sample from intestine and spleen were taken, fixed in formalin and embedded in paraffin. Using a microtome, tissue sections of 4 μm in thickness were produced, and they were then stained with hematoxylin and eosin. Goblet cells in the intestinal mucosa were counted, and melanomacrophage center (MMC) regions in the splenic parenchyma were measured as indicators of mucosal defense and chronic stress response, respectively. Statistical analyses were conducted using a linear mixed model; significance was set at $p<0.05$.

## Results

A significant difference was found in goblet cell counts (Fig. 1) among diets ($p<0.05$), with higher counts in the control group. However, inflammatory signs, particularly hyperplasia, were sporadically noted in fish fed L1 and H1 diets. The MMCs (Fig. 2) percentage coverage in the spleen did not show any significant variation among dietary treatments.

## Discussion

The lower number of goblet cells in fish fed the L1 and H1 diets suggests that these formulations did not cause a mucosal defense response in the intestine. However, the presence of intestinal inflammation indicates that alternative protein sources—despite being associated with no significant systemic stress responses and lower goblet cell counts—may still impact gut health in gilthead seabream broodstock. Splenic histology, like the measured stress biomarkers, appeared unaffected.

## Conclusion

Although the different diets did not induce oxidative or stress-related responses, the observed intestinal histological alterations suggest that further investigation into gut inflammatory responses is warranted to ensure these dietary formulations do not compromise the performance and welfare of gilthead seabream.

**Introduction**

The greater amberjack (Seriola dumerili) is a promising candidate for diversifying marine aquaculture because of its rapid growth and consumer acceptance. However, it requires high levels of protein, mainly from fishmeal. Therefore, developing plant-based diets that support good growth rates and encourage sustainable sector development is essential. The lower digestibility and availability of plant ingredients can negatively impact fish health. To address this, strategies are needed to improve the absorption and digestibility of plant-rich diets. One such approach involves enhancing the uptake of diets high in plant ingredients through biotechnological pre-treatments, such as enzymatic hydrolysis and/or supplementing with nutraceuticals derived from algae. We assessed the impact of partial fishmeal replacement with plant proteins (PP) and an algal-supplemented plant-based diet (PPLB) on the composition and function of intestinal microbiota.

**Materials and Methods**

Fish were reared in 400 L tanks at 22°C and 37‰ salinity, fed ad libitum for 69 days. Three isoproteic and isolipidic diets were tested: FM (fish meal), PP (50% fishmeal replacement by plant protein with biotechnological pre-treatment), and PPLB (PP + 3% algal nutraceutical). Anterior intestinal sections (mucosa plus digesta) from six fish per group were preserved in DNA/RNA Shield. Microbiota was analysed via 16S rRNA sequencing (Illumina NextSeq, 600 cycles, P1 Kit, V3–V4 region, Zymo Research). DADA2 and QIIME were used for denoising and taxonomic classification. LEfSe identified diet-associated microbial biomarkers.

**Results**

Phylum-level composition showed dominance of *Proteobacteria* and *Firmicutes* across all diets, with *Actinobacteria* enriched in PPLB. LEfSe identified 31 discriminant taxa: PPLB (17), FM (8), and PP (6). PPLB diets enriched *Propionibacterium*, *Rothia*, *Dechloromonas*, *Carnobacterium*, *Marinobacter*, and *Nocardioides*, which are taxa linked to fermentation (associated with SCFA production), immunomodulation, and adaptation to algal substrates (Nakamura *et al*., 2020; Xiao *et al*., 2022, Pinto *et al*., 2021). FM-associated taxa included *Veillonellaceae* and *Negativicutes*, suggesting a core anaerobic commensal community (Facchin *et al*., 2024).

PP enriched mainly environmental taxa (e.g., *Paraburkholderia*), with limited functional specialisation. This limited microbial adaptation may reflect decreased digestibility or absence of bioactive compounds in non-supplemented plant-based diets.

The cladogram visualising phylogenetic relationships among the identified biomarkers supported the compositional findings (Fig. 1). Taxa enriched in PPLB clustered into well-defined clades, particularly within *Actinobacteria* and *Proteobacteria*, indicating coordinated shifts in microbial lineages in response to dietary supplementation. PP-associated biomarkers appeared more phylogenetically dispersed, suggesting less targeted adaptation of the microbiota. FM-associated taxa clustered into anaerobic and mucosa-adapted branches, consistent with their ecological roles.

*(Continued on next page)*

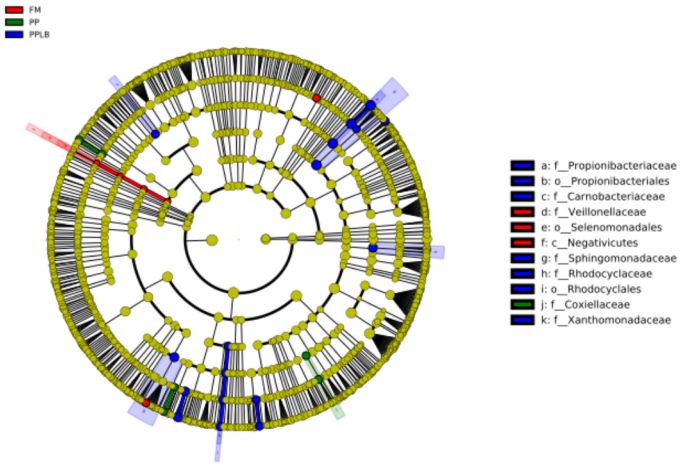

**Figure 1.** Phylogenetic cladogram of bacterial taxa differentially abundant across diets. Taxa are colour-coded by diet and enrichment type and arranged according to their taxonomic hierarchy. Converging clades highlight coordinated lineage-level shifts, particularly in the PPLB group.

Conclusion

The algal-supplemented PPLB diet promoted a diverse, functionally enriched intestinal microbiota in *S. dumerili*, whereas the PP diet alone induced limited adaptation. These findings support the use of biotechnologically enhanced algal nutraceuticals to improve gut health in sustainable aquafeeds.

## Introduction

Salmonids are sensitive to low dissolved oxygen (DO) levels, with sudden drops often triggered by high temperatures, fish density, or handling. Climate change may increase the frequency of such events, affecting fish welfare and performance. Antioxidant micronutrients like selenium, vitamin C, and astaxanthin are promising tools to enhance stress resilience. Selenium supplementation has been shown to improve hypoxia tolerance in trout fry fed plant-based diets (Wischhusen et al., 2020), with evidence suggesting sex-related differences in oxidative stress responses (Schomburg and Schweizer, 2009). Krill meal (KM), naturally rich in antioxidants, has shown benefits for growth, flesh quality, and fish health (Kaur et al., 2022, Tran et al., 2025). This study investigated the effects of KM on juvenile rainbow trout performance, antioxidant responses under hypoxia, and sex-related metabolic differences.

## Materials and methods

Four experimental diets were tested: a control diet (CTRL) containing 10% fishmeal, and three diets in which krill meal (KM) replaced the marine fraction (fishmeal + fish oil) at 5% (KM5), 7.5% (KM7), and 10% (KM10). Groups of 60 juvenile rainbow trout (37 ± 1 g), of mixed sex, were randomly distributed into triplicate tanks per treatment and fed their respective diets for 12 weeks at 17 ± 1 °C, with DO maintained above 9 mg/L. At the end of the feeding period, 30 fish per tank were euthanized for tissue collection. The remaining fish were subjected to chronic hypoxia (< 6 mg/L DO) for an additional 3 weeks before final sampling. Growth performance, feed intake, and survival were monitored throughout the trial. Feces were collected by stripping for digestibility analysis. Fillet color, sex, whole-body composition, liver antioxidant status, plasma stress indicators, and blood proteomic profiles were assessed. Data were analyzed by ANOVA and presented as means ± SEM.

## Results

Fish fed the KM7 diet showed improved growth performance both before and after the chronic hypoxia challenge (Fig. 1A). Chronic hypoxia significantly reduced fillet redness, whereas KM inclusion enhanced it in a dose-dependent manner, likely due to its natural astaxanthin content, as all KM groups showed higher redness than the control both before and after hypoxia (Fig. 1B).

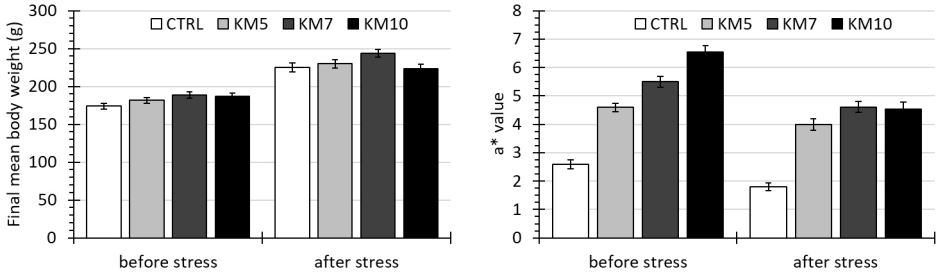

Fig. 1. Growth performance (A) and fillet color with the intensity in red (B) in juvenile rainbow trout fed the experimental diets before and after hypoxia

*(Continued on next page)*

**Discussion**

This study shows that KM inclusion improves growth performance and fillet quality in juvenile rainbow trout, particularly under chronic hypoxia. The 7.5% KM diet (KM7) was especially effective, suggesting that antioxidant-rich ingredients such as KM can enhance fish resilience to oxygen deprivation. Improved fillet redness under hypoxic conditions, likely linked to dietary astaxanthin, further supports this protective effect. These findings are consistent with previous work by Kalinowski et al. (2019), who demonstrated that dietary astaxanthin improved hepatic oxidative stress tolerance in trout exposed to hyperoxia. The antioxidant components of KM, including astaxanthin and selenium, may thus play a key role in mitigating stress-induced oxidative damage.

A notable finding is the potential for sex-dependent differences in hypoxia responses. Ongoing analyses aim to determine whether the effects of KM differ between males and females, particularly regarding antioxidant pathways. Previous studies have reported sex-specific oxidative stress responses (Schomburg and Schweizer, 2009), but these remain to be fully characterized in the present study. Further investigation of liver antioxidant status, plasma stress markers, and whole-body composition will provide deeper insights into the physiological adjustments associated with hypoxia and KM supplementation.

**Conclusion**

KM appears to improve hypoxia tolerance in rainbow trout, potentially through its antioxidant properties and with possible sex-specific effects. These results have important implications for aquaculture, offering a nutritional strategy to enhance fish welfare and performance under climate-induced environmental stress.

# HOW ACTIVATION SOLUTIONS AFFECT FERTILIZATION OF SIBERIAN STURGEON *Acipenser baerii* EGGS ?

Dorota Fopp-Bayat, Beata Irena Cejko, Agnieszka Kołosińska

Department of Ichthyology and Aquaculture, Faculty of Animal Bioengineering
University of Warmia and Mazury in Olsztyn
Oczapowskiego 5
10-719 Olsztyn, Poland
E-mail: foppik@uwm.edu.pl

**Introduction**

The success of fertilization of sturgeon eggs depends on the condition and maturity of the spawners (females and males), the procedure of controlled spawning and incubation of the eggs. It is important to have ichthyological experience and the ability to apply modern methods of sturgeon reproduction biotechnology, considering the analysis of gamete quality and the use of optimal activation solutions. Sturgeon spawning can be carried out at optimum levels if all the above factors are considered.

**Material and Methods**

The present study was conducted with six male and two female Siberian sturgeon *Acipenser baerii* to test and optimise fertilisation using five activation solutions. Semen collected from 6 male Siberian sturgeon was used to fertilise Siberian sturgeon eggs using five experimental activation solutions: AS1, AS2, AS3, AS4, AS5 which differed in composition, pH and osmolality. At 4 hours after activation, the degree of fertilisation was analysed and the percentage of alive normal and abnormal embryos was determined.

The SCA semen analysis system (Microptic, Spain) was used for semen analysis. The following parameters were analysed in semen activated with the five activation fluids mentioned above: sperm motility (MOT; %), velocity of curvilinear movement (VCL; μms-1), ALH, PRG, LIN, BCF.

**Results**

The highest percentages of sperm motility and curvilinear velocity were observed in the group activated with the AS2 solution, while the lowest percentages were observed in the group activated with the AS3 solution. The highest percentage of fertilised eggs 4 hours after activation was observed in the group activated with AS1 and AS2 solutions, and the lowest in the AS5 activation solution. The presented research results showing the use of optimal fertilization solutions can provide valuable guidance for breeders involved in the reproduction and hatching of sturgeon

# OVERVIEW OF PLASTIC AQUACULTURE EQUIPMENT USED IN NORWEGIAN SEA BASED FISH FARMS

H.M. Føre[1*], N. Blöcher[1], M.A. Mulelid[1]

[1]SINTEF Ocean
Postboks 4762 Torgarden
NO-7465 Trondheim, Norway
E-mail: Heidi.moe.fore@sintef.no

## Introduction

Most Norwegian fish farms consist of plastic (polymer) structures such as floating platforms made of polyethylene pipes, nets made of nylon yarn, and moorings of synthetic ropes. During recent years, discarded aquaculture structures are increasingly considered a resource for reuse or recirculation of materials. Estimates from 2017 indicated that Norwegian Aquaculture facilities consisted of up to 192 000 tons of plastic components (Hognes & Skar, 2017; Sundt et al., 2018).

To establish sustainable circular business models, it is essential to understand which plastic resources, i.e. used equipment, that will be available during the next years. Thus, an early goal in the SirkAQ project (https://sirkaq.com/) has been to establish an overview of types and amounts of polymer materials in Norwegian fish farming structures.

## Materials and methods

This work includes an analysis of the amount, geographic location, composition, quality, age and condition of plastic components used in sea-based farms during 2022. It is limited to plastic components of large volumes, i.e. floaters, nets and mooring lines, and feed pipes due to their frequent replacement.

Nine in-depth interviews of suppliers of plastic equipment were the main source of information. Semi-structured interviews were performed with the goal of answering the following research question: How much plastic can be found in Norwegian fish farms at sea, and what properties do they possess that are important to consider when deciding on their future use?

In the analysis, biomass reports (https://www.fiskeridir.no) and literature (McIntosh et al., 2022) were used to establish the number and geographic location of farms and floaters used in 2022.

## Results

We have estimated that a total of 5800 plastic fish pens could be found in Norwegian fish farms during 2022. About 91% of Norwegian fish pens were made of mainly plastic materials. There were 823 active fish farms along the Norwegian coastline, also including a minority of traditional steel cages and new types of fish farms (Føre et al., 2022).

Norwegian fish farms consisted of about in total 230,000 tonnes of plastic during 2022. The total amount of plastic in floating collars and bottom rings was about 175,000 tonnes. There were about 30,000 tonnes of nets in use, 21,000 tonnes of ropes in the mooring systems, and 3,300 tonnes of feed hoses. The analysis shows that over 80% of the mapped plastic was Polyethylene (PE), of which 66% was virgin HDPE 100. Furthermore, we found 10% Nylon, 6% polyolefins in the form of PE/PP, 3% PE/PET, and 1% UHMWPE. There are also smaller amounts of Polypropylene (PP).

The typical practical lifetime is around 15 years for cage collars, about eight years for nets (including storage between use), 10 years for mooring lines, and on average 1.5 years (one production cycle) for feed pipes. The plastic materials in discarded equipment are often in good condition.

*(Continued on next page)*

# MONITORING LOADS AND MOVEMENTS OF SUGAR KELP (*Saccharina latissima*) CULTIVATION LINES IN AN IMTA FARM

H.M. Føre[1*], O.J. Broch[1], B.S.B Kristensen[2], S. Forbord[1], P.C. Endresen[1], T. Marstrand[3]

[1]SINTEF Ocean, Postboks 4762 Torgarden, NO-7465 Trondheim, Norway
[2]NTNU Department of Biology, 7491 Trondheim, Norway
[3]Folla Alger, Nordfoldveien 202, 8286 Nordfold, Norway
E-mail: Heidi.moe.fore@sintef.no

## Introduction

Integrated multi-trophic aquaculture (IMTA), involves farming of multiple marine species at different trophic levels at the same aquaculture site. In the AURORA IMTA project, integrated aquaculture of Atlantic salmon (*Salmo salar*) and the brown macroalgae called sugar kelp (*Saccharina latissima*) is realized and developed at a full-scale sea-based facility in the North of Norway. Possible benefits of IMTA are currently investigated along with developing robust solutions for both biological production and structural design The main idea is that the kelp can benefit from absorbing dissolved inorganic nutrients from the salmon farming. In addition, their joint production may be an effective shared use of sea area.

A part of the current RnD-work includes developing knowledge to ensure a safe and effective design of such IMTA-farms. Currently there is little knowledge on expected loads from waves and currents (hydrodynamic loads) on seaweed cultivation lines (Endresen et al., 2019; Kool et al., 2022), and seaweed weight (hydrostatic loads). This results in application of unnecessarily high safety factors in design, which may result in sub-optimal and overly expensive farm designs. In addition, increased knowledge of possible displacements and movements of cultivation lines is of great interest, as this may affect growth (through e.g. light, temperature and water quality) and lead to line entanglement and seaweed abrasion.

## Materials and methods

Five cultivation lines with sugar kelp have been instrumented with two depth sensors and a load chackle each from April 25$^{th}$ to July 10$^{th}$ 2024. In addition, the mass density of the kelp was measured once or twice a month to facilitate weight calculation.

Initial numerical analysis indicated that cultivation lines were horizontal at high hydrodynamic loads, while they were sagging in calm water. Based on these findings, the experiment was designed to investigate the following hypotheses:

1. The kelp line position will vary both horizontally and vertically due to currents, waves and seaweed growth.
2. Hydrodynamic loads on cultivation lines can be found from load measurements during periods when depth sensors indicate horizontal line positions.
3. At maximum line sagging in calm water, the seaweed weight may be found from load measurements.
4. Mass density of seaweed can be found using Archimedes principle and measurements of weight and volume of seaweed and seawater

Since the kelp would easily decompose during unfavourable storing conditions, our tests were done in the field using newly harvested seaweed kept in fresh seawater.

## Results

All instruments, including five load chackles and ten depth sensors, worked well and produced continuous measurement data except during two periods of power failure. The findings supported all four hypotheses, also indicating that the developed methods for measuring of load, position and mass density worked well.

Vertical kelp line positions varied with several meters, and large sagging coincided with low measured loads. Peaks in load measurements coincided with horizontal lines (similar depth measurements over a line) positioned at relatively shallow waters.

*(Continued on next page)*

A method and procedure to measure mass density of seaweed (hypothesis 4) was developed and employed. The results showed that the kelp had a mass density of 920 ± 86 kg/m3, based on 14 separate measurements. This is lower than seawater, and it was observed that the kelp was floating (without visible air-bubbles). Previous literature has indicated a mass density of about 1100 kg/m3, i.e. slightly higher than water (Vettori & Nikora, 2017; Norvik, 2017). Possible reasons for this may be that the density may depend on site specific conditions like nutrients, kelp size and carbon content, morphology (Buck & Buchholz, 2004) or different treatment and storing of the kelp after harvesting.

## Introduction

The aquaculture industry is shifting from manual operations and experience-based reasoning towards a more objective, data-driven approach to meet growing global seafood demand and support the expansion of salmon farming into larger and more exposed offshore sites. This shift is driven by the integration of intelligent sensors, mathematical models, and decision support or autonomous systems across production stages, aiming to increase productivity, enhance sustainability, and improve fish welfare. This study presents a stereo vision framework for automated fish monitoring in finfish aquaculture, enabling tasks such as fish detection, tracking, behaviour identification, and size measurement. The proposed frame reduces the need for intrusive or labour-intensive monitoring methods, providing a more precise and efficient foundation for fish stock management.

This work was financed by the Research Council of Norway through the project: CHANGE – An underwater robotics concept for dynamically changing environments [1].

## Materials and methods

Stereo videos of salmon fish were collected from two separate experiments at SINTEF's industrial-scale research fish farm site, Korsneset [2], in September 2022 (P1) and March 2023 (P2). P1 aimed to investigate fish behavioural responses to intrusive objects with varying appearance. A central structure, equipped with a stereo camera (comprising two synchronized Lucid TRI032S-CC GigE cameras) on top and two Ping360 sonars (one on top and the other on the bottom), was decorated in six different configurations varying in shape, size, and colour. The average fish weight during P1 was 1 kg. P2 was designed to study the impact of Remotely Operated Vehicle (ROV) motion on fish behaviour. The ROV was equipped with the same stereo camera setup as in P1, and the average fish weight during P2 was 3.5 kg.

The proposed framework employs two independent YOLOv8 models: one dedicated to fish detection using Oriented Bounding Boxes (OBBs), and the other focused on anatomical landmark identification through integrated keypoint detection. The approach began with stereo camera calibration to correct lens distortions and establish spatial relationships between the left and right views. Two custom training datasets were then created by annotating fish with OBBs and labelling specific body parts of the fish such as the mouth and fins to train the respective models. During deployment, each stereo video frame is first split into a calibrated and aligned left-right image pair. The OBB detection model is then applied to both images to detect fish, with detections in the left image tracked using the ByteTrack algorithm [3]. The keypoint detection model is subsequently used to localise desired anatomical landmarks on each detected fish body. Hungarian algorithm [4] thereafter associates the tracked fish and their keypoints in the left image with corresponding detections in the right. Disparities are computed from these associations and used to estimate depth and 3D coordinates through the pre-determined calibration parameters and triangulation geometry. This spatial reconstruction enables further estimation of fish 3D swimming trajectories and motion patterns by continuously tracking positions of body parts across frames, as well as measuring fish length by calculating the distance between the mouth and central caudal fin keypoints.

## Results

Figure 1a illustrates keypoint tracking, where the centre of the OBB, mouth, gill, and caudal fin of an individual fish were identified and tracked. These keypoints were used to generate detailed 3D trajectories and motion patterns, as visualised in Figures 1b and 1c. The results revealed distinct motion patterns across different body parts: the caudal fin displayed the most dramatic speed variations, followed by the mouth, while the gills and OBB centers showed comparatively lower variability across all metrics.

*(Continued on next page)*

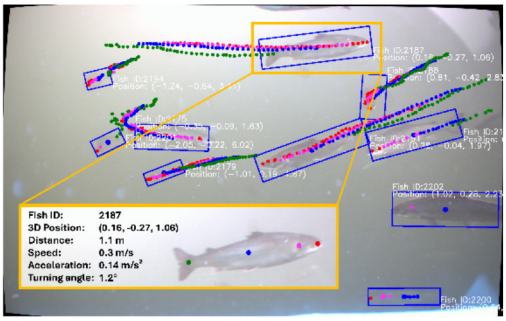

***Figure 1a:*** *Tracked fish illustrating detected keypoints and their 3D trajectories.*

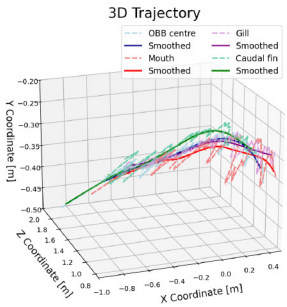

***Figure 1b:*** *3D trajectory of fish no. 2187.*

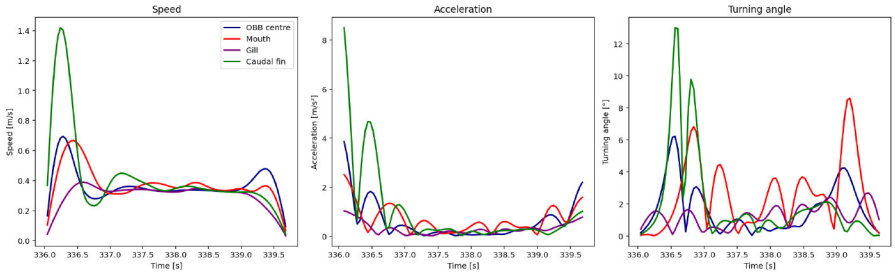

***Figure 1c:*** *Motion characteristics of fish no. 2187.*

Fish body lengths estimated from the stereo videos were 39 cm for P1 and 56 cm for P2. To validate these measurements, a weight-length relationship based on commercial farm data [5] was used to calculate reference body lengths of 41 cm and 63 cm for P1 and P2, respectively. The stereo video estimates closely match the reference lengths, demonstrating the reliability of our length estimation methodology and highlighting its potential for future applications.

**Conclusion and future work**

The proposed stereo vision framework, utilising OBB-based object detection and keypoint detection models, provides a robust, automated, and non-invasive solution for fish monitoring in aquaculture. Future developments will aim to integrate the two detection models into a unified end-to-end network to enhance processing speed. Additionally, extending the number of detectable keypoints will allow for capturing the contours and natural curvature of the fish body, providing a more accurate representation of its morphology for detailed sizing and behavioural analysis.

# EVALUATION OF COMMERCIAL PHYTASE ENZYMES ON DIGESTIBILITY AND GROWTH PERFORMANCE IN FEED FOR *Sparus aurata*

Pierre Fortin*, Sophie Reays, Nicolas Tanrattana

TECHNA
41 Rte de St Etienne de Montluc
44220 Couëron, France
nicolas.tanrattana@groupe-techna.com

Phosphorus plays an important role in animal growth, especially for bone formation. In current feed, inorganic phosphorus (MCP, DCP) is commonly used to fulfill needs of fish. Phytic acid, is found in plant and constitutes an unused reservoir of phosphorus in feeds. Furthermore, phytic acid is an antinutritional factor affecting other nutrients such as amino acids, or minerals availability by binding them.

TECHNA tested 3 different phytases in feed deficient in phosphorus to evaluate their effects on digestibility and zootechnical parameters on Gilthead seabream (Sparus aurata), at the Hellenic Centre for Marine Research (HCMR). Phytase, named G, H and K for confidentiality comes from different phytase suppliers.

Six diets were designed for this experiment, three controls with varying level of phosphorus (0.3, 0.45 and 0.6% digestible phosphorus), designed to validate the phosphorus dose response. Three test diets with the same formula as the 0.3% digestible phosphorus value plus the addition of phytase. Phytase levels in feed were calculated based on supplier recommendation and therefore differ (1000 to 1500 FTU or u/g). All feeds were similar for 98% of their composition. Monocalcium phosphate was used for the 0,6% digestible phosphorus diet and replaced by calcium carbonate partially or fully to reach 0,45 and 0,3% feeds.

In HCMR facilities, 40 seabreams with an initial weight of 16.2 ± 0.04g were stocked in tanks filled with salt water at a temperature of 23-25°C. Each treatment was done in triplicate. The growth phase lasted 76 days and was followed by a two-weeks digestibility phase.

Phosphorus ADC was improved in diets containing phytase G and K compared to its respective control (Negative or 0.3%).

The results showed that the higher the phosphorus was, the better were the performances (FCR and final weight). Only phytase G had higher final weight but remain closer to negative control than intermediate control (expected growth).

| Treatment | Phosphorus ADC (%) | Protein ADC (%) | Fat ADC (%) |
|---|---|---|---|
| Negative control | $12.85 \pm 1.47^{c}$ | $92.15 \pm 0.95^{cd}$ | $74.86 \pm 0.73^{c}$ |
| Intermediate control | $49.34 \pm 1.90^{a}$ | $95.56 \pm 0.17^{a}$ | $80.48 \pm 1.07^{b}$ |
| Positive control | $52.80 \pm 2.14^{a}$ | $95.44 \pm 0.57^{ab}$ | $85.38 \pm 1.01^{a}$ |
| Phytase G | $24.94 \pm 1.82^{b}$ | $93.61 \pm 0.14^{bc}$ | $79.61 \pm 1.51^{b}$ |
| Phytase K | $26.74 \pm 0.54^{b}$ | $91.58 \pm 1.24^{d}$ | $82.27 \pm 1.83^{ab}$ |

Figure 2. Digestibility coefficient of feeds fed to Gilthead Seabream (*Sparus aurata*)

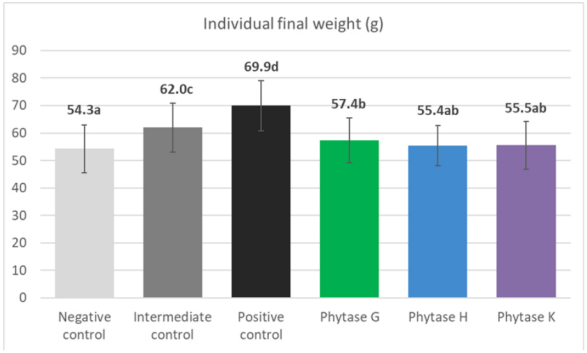

Figure 2. Final weight of Gilthead Seabream (*Sparus aurata*) fed the different diets

In conclusion, even if phytase were able to increase phosphorus digestibility, it was not sufficient to improve growth and FCR to the expected value. Digestible phosphorus valorization following this trial result was far from the supplier's recommendation (0.15% digestible phosphorus).

# BIODEGRADABLE CONTAINERS AS ALTERNATIVE FOR FISH SPERM CRYOPRESERVATION

## Introduction

Nowadays, the most used fish sperm cryo-containers are straws made of polypropylene or polyvinyl chloride (PVC). They cannot be reused, making them waste with a high potential for polluting the environment. Thus, we aimed to assess the efficiency of hard-gelatin and hard-hydroxypropyl methylcellulose (HPMC) capsules as biodegradable alternative containers to plastic straws for fish sperm cryopreservation.

## Material and Methods

South American silver catfish *Rhamdia quelen* sperm samples (n = 12) were cryopreserved in 5% D-fructose + 5% powdered milk + 10% methanol diluted in a ratio 1:4 (sperm: cryo-solution). European eel *Anguilla anguilla* sperm samples (n = 12) were cryopreserved using P1 extender + 5% egg yolk + 10% methanol diluted in a ratio 1:9 (sperm: cryo-solution). Gilthead seabream *Sparus aurata* sperm samples (n = 12) were cryopreserved in NAM (non-activating medium) extender with 10% dimethyl sulfoxide (DMSO) after dilution in a ratio 1:6 (sperm: cryo-solution). European sea bass sperm samples (n = 10) were diluted in NAM at 1:5.7 (sperm: NAM), and 5 % DMSO was added. Sperm samples of all species, with motility over 60%, were individually cryopreserved in plastic straws, hard-gelatin, and hard-hydroxypropyl methylcellulose (HPMC) biodegradable capsules. All the containers were filled (silver catfish and seabream – 0.25 mL; eel and sea bass – 0.5 mL) and cryopreserved in liquid nitrogen vapor. The straws were thawed in a water bath (silver catfish 25 °C/10 s, eel 40 °C/13 s, seabream 60 °C/5 s, and sea bass 35 °C/ 15 s), and the capsules were thawed and dissolved into a plastic tube (15 mL) containing a previously warmed extender (5 mL- silver catfish 25 °C, eel and seabream 40 °C, and sea bass 35 °C) under shake in a vortex for 25 s.

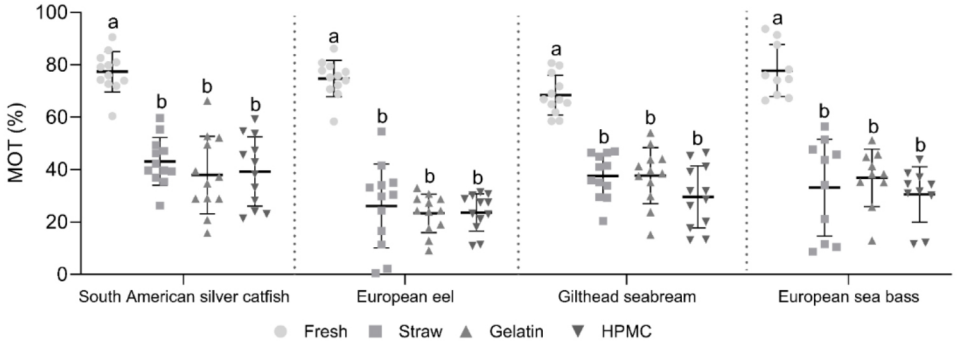

Figure 1. Fresh and post-thawed sperm motility (MOT) of South American silver catfish (n = 12), European eel (n = 12), gilthead seabream (n = 12), and European sea bass (n = 10) evaluated by CASA-Mot. The samples were cryopreserved in plastic straws, hard-gelatin, and hard-HPMC capsules. Values are shown individually, and horizontal lines indicate the means ± SD. Different letters indicate differences ($P < 0.05$; Tukey's test) between means.

*(Continued on next page)*

Total motility (MOT - %), curvilinear (VCL - μm/s), straight line (VSL - μm/s), and average path (VAP - μm/s) velocities were evaluated by CASA-Mot software. Rates of fertilization, hatching, and normal larvae morphology were determined using silver catfish post-thawed sperm. The alkaline comet assay was performed to quantify sperm DNA damage of eel, gilthead seabream, and sea bass. Tail-DNA (%) was evaluated using CaspLab software.

**Results**

In all four species, sperm cryopreservation led to a MOT decrease in all the storage containers (Fig. 1). Nonetheless, no significant differences in MOT were found between samples preserved in capsules and straws. A similar result was observed in sperm velocity parameters. Eel sperm cryopreserved in straws retained velocity values comparable to fresh samples, while those stored in gelatin capsules preserved their VSL and VAP post-cryopreservation. For sea bass, sperm stored in gelatin capsules exhibited higher velocities than those preserved in HPMC capsules.

There was no difference between straw and capsules in silver catfish fertilization, hatching, and normal larvae rates. Cryopreservation did not result in detectable DNA fragmentation in eel and sea bass sperm. Conversely, Tail DNA of gilthead seabream sperm cryopreserved in gelatin (10 ± 2%) and HPMC (11 ± 6%) capsules increased after thawing when compared to fresh (4 ± 3%) and straw-stored (4 ± 1%) samples.

**Discussion**

During cryopreservation, cells are exposed to high thermal and osmotic stress, mainly during freezing and thawing, causing damage to the cells (Mazur et al., 1972) and impairing sperm motility of all four species. However, the kinetic parameters of sperm samples cryopreserved in straws and capsules did not differ. It was noted that silver catfish samples cryopreserved using all three container types achieved fertilization rates of approximately 70%, a value considered high according to Beirão et al. (2019). We did not observe increased sperm DNA damage in European eel and sea bass after freezing and thawing. However, we observed a Tail DNA of 10 and 11% in sperm cryopreserved in gelatin and HPMC capsules, respectively. These results indicate low sperm DNA damage, and the oocyte could probably repair this level of damage during early embryogenesis.
Based on our results, hard-gelatin and HPMC biodegradable capsules can be an alternative to plastic straws for South American silver catfish, European eel, gilthead seabream, and European sea bass sperm cryopreservation.

# DEVELOPMENT OF CHALLENGE TESTS TO SELECT SPERM SAMPLES FROM MEDITERRANEAN FISHES BEING RESILIENT TO CLIMATE CHANGE

T.S. França[1]*, W.A. González-López[1], F. Fernández-García[1], A. Belenguer[2], P.G. Holhorea[2], J. Calduch-Giner[2], A. Felip[2], E. Mañanós[2], N. Ducan[3], A. Gómez [2], J. Pérez-Sánchez[2], L. Pérez[1] and J.F. Asturiano[1]

E-mail: thalesfranca@gmail.com

**Introduction**

Climate change impacts the marine environment, which faces acidification and rising temperatures. As key fishes in Mediterranean aquaculture rely on external fertilization, these environmental changes can impair sperm quality and reproduction. Therefore, we aimed to evaluate the effect of temperature and pH of artificial seawater (ASW) on the activation of sperm from different aquaculture Mediterranean species. Furthermore, sperm evaluation was used to select resilient males and to form a germplasm bank with climate change resistant samples.

**Material and Methods**

European sea bass, *Dicentrarchus labrax* (n = 30), gilthead seabream, *Sparus aurata* (n = 93), and Senegalese sole, *Solea senegalensis* (n = 116) sperm samples were collected at the Institute of Aquaculture Torre de la Sal (IATS - CSIC). In addition, samples from S. sole males (n = 16) were collected at the Institute of Agrifood Research and Technology (IRTA). Samples were obtained by abdominal pressure, diluted in species-specific extenders (NAM or Ringer solution) and transported at 4 °C to the Universitat Politècnica de València (UPV). At UPV, sperm motility was analyzed using a CASA-Mot system after activation with ASW. Only samples with more than 50% motility were used for further experiments.

Three challenge tests were tested trying to identify sperm samples that were resilient to environmental pH and temperature variations. The first one was the sperm activation using ASW at different pH (6.5, 7.2, 7.4, 7.6, 7.8, 8, 8.2, 9.5). The second challenge test was the sperm activation with ASW at different temperatures (seabream and S. sole: 4, 16, 22 °C; sea bass: 4, 12, 20 °C). The third one evaluated the combined effect of ASW pH and temperature: pH (7.8 and 8.2) x (seabream and S. sole: 4, 16, 22 °C; sea bass: 4, 12, 20 °C). Before activation, the samples were incubated (~1h) at the same temperature.

The challenge test combining seawater pH and temperature was the most effective for selecting resilient males. Therefore, sperm samples from sea bass (n = 10), seabream (n = 43), and S. sole (n = 10) were subjected to challenge test 3. Males were selected according to the variation in the MOT percentage obtained by applying variations caused by climate change (acidification and temperature increase) compared with the natural environment during their reproductive periods (pH 8.2; sea bass, 12 °C; seabream and S. sole, 16 °C). Males were selected considering the variations on sperm motility in comparison with values obtained under natural conditions. Different selection thresholds can be applied: up to 5% variation for a rigorous level, up to 10% for a less rigorous level, and up to 15% for S. sole samples.

**Results**

No practical differences were observed in the motility of the three species when challenge tests 1 and 2 were applied. However, in challenge test 3, it was clear that acidification and warming of the marine environment affected the sperm quality of the three Mediterranean species. The temperature increase impaired the sea bass (Fig. 1A) and S. sole sperm (Fig. 1B), and the decrease in ASW pH affected the MOT of sea bream sperm (Fig. 1C).

After applying the challenge test 3, 6 sea bass were selected at a 5% variation level and 7 at up to 10% variation concerning the MOT values obtained with the natural parameters of pH and temperature during the reproductive period. For seabream, 18 males at 5% variation level and 32 males at up to 10% level were selected. Only 1 S. sole male at the 5% and 2 at 10% variation levels were selected. At the 15% level, 6 breeders were selected.

*(Continued on next page)*

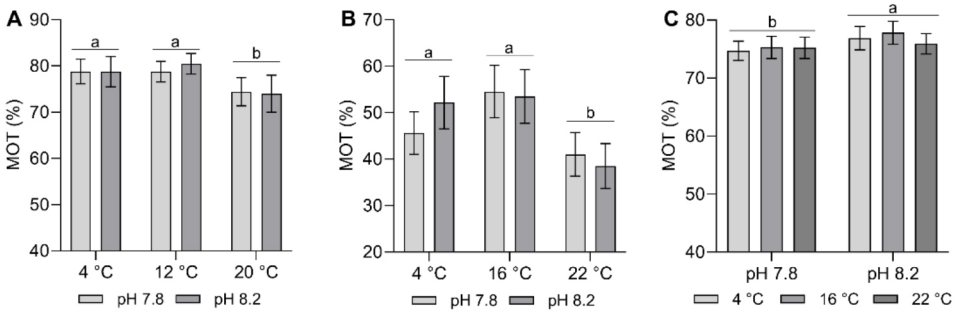

Figure 1. European sea bass (A – n = 10), Senegalese sole (B – n = 10), and gilthead seabream (C – n = 20) sperm motility (MOT - %) evaluated by CASA-Mot after activation using artificial seawater (ASW) at the same incubation temperature and pH adjusted to 7.8 and 8.2.

## Discussion

Environmental pH and temperature influence sperm motility (Alavi & Cosson, 2005). Sperm of some species can resist slight environmental acidification, as was observed in sea bass and S. sole in the present study. However, seabream sperm was impacted by acidification. Sperm activation in a more acidic environment may have caused a reduction in the membrane potential of sperm mitochondria since seminal plasma alkalization is necessary for sperm activation to occur (Alavi & Cosson, 2005). Increasing the incubation and activation temperature did not affect seabream sperm, while impaired sea bass and S. sole sperm motility. The sperm activation using above-normal temperatures leads to a decline in sperm motility, probably due to the limited antioxidant enzyme efficacy in mitigating oxidative stress (Dadras et al., 2017).

Alterations in pH and temperature driven by climate change impacted the sperm quality of three Mediterranean aquaculture species. The developed challenge tests showed to be a valuable technique for identifying males resilient to such environmental stressors, whose genetic material can be conserved in germplasm banks.

**Introduction**

Marine biotechnology is increasingly recognised as a key approach to understanding and harnessing the potential of marine bioresources, while also supporting the development of tools and technologies to explore them. Emerging products, processes, and techniques have the potential to contribute significantly to the sustainable development of the blue bioeconomy. Ocean, marine biodiversity, and biomass hold vast untapped potential that marine biotechnology could help unlock, particularly in the context of global challenges such as food security, energy, and health.

The regions of the European Atlantic Area face both complex challenges and promising opportunities across a range of marine sectors. This underscores the need for a coherent, regionally harmonised strategy to ensure marine biotechnology advances equitably and efficiently across the Atlantic basin. Realising its full potential requires the alignment of knowledge gaps, improved technology transfer, and effective policy integration.

This study adopts a stakeholder-driven approach to explore marine biotechnology across the European Atlantic basin. The findings aim to inform initiatives that support innovation, competitiveness, and sustainable growth in the Atlantic marine biotechnology sector.

**Materials and methods**

Two rounds of participatory workshops were conducted in 2024 and 2025, totalling 12 workshops across eight Atlantic regions in Portugal, France, Ireland, and Spain. A diverse group of stakeholders representing the quadruple helix model (industry, academia, public sector, and civil society) ensured an inclusive, multi-stakeholder perspective.

Each workshop followed a structured approach, beginning with a pre-survey to identify key challenges and plan the organisation of working groups. During the workshop day, participants were introduced to three pre-defined Blue Biotechnology categories: (1) sustainable and resilient aquaculture, (2) omics and marine observation technologies, and (3) marine-derived products for industrial use. Depending on the number and expertise of attendees, they were divided into working groups or round tables. A collaborative affinity mapping approach was used. Discussions focused on identifying challenges and proposing potential solutions, using physical or digital post-its for input collection.

*(Continued on next page)*

The collected data was analysed into specific challenges and potential solutions. A total of 307 challenges were reported, all under the three thematic areas. These were further mapped using the PESTEL framework (Political, Economic, Social, Technological, Environmental, and Legal).

**Results and discussion**

Across the two years of stakeholder engagement, a total of 307 challenges were identified (153 challenges in 2024 and 154 in 2025), predominantly concentrated in the Technological (36%), Environmental (21%) and Economic (20%) domains of the PESTEL framework. The challenges reflect key technical barriers such as inefficiencies in extraction processes, scaling difficulties, limited knowledge transfer and weak industry-academia collaboration, and gaps in circular economy implementation. Political, Social, and Legal domains represented 23% of the total, highlighting licensing and regulatory complexities, funding constraints, stakeholder engagement gaps, intellectual property (IP) concerns and social acceptance issues.

The challenges identified were distributed across three priority areas (1) sustainable and resilient aquaculture (46%), with emphasis on climate-adaptive practices, circular approaches, sustainable feed alternatives, and diseases management. (2) Omics and marine observation technologies faced challenges (26%) around data integration, technological readiness, and ensuring interoperability of systems for comprehensive monitoring. (3) Industrial use of marine-derived resources (28%) identified needs related most with reproducibility, standardization, high production costs, regulatory approval, and market acceptance, underlining the critical gap between innovation and commercialization.

Stakeholders consistently identified two critical vectors across the three thematic areas: (a) the need for scientific and technological advancements, particularly in scaling-up processes, circular biomass valorisation, and technological readiness; and (b) enabling non-technological elements such as regulatory clarity, IP protection, streamlined approval pathways and market acceptance.

**Conclusions**

This study highlights the complex and region-specific challenges facing the development of Marine Biotechnology in the European Atlantic Area, emphasising the need for integrated policy and innovation frameworks. Stakeholder insights, when combined with strategic policy analysis, provide the foundation for cross-border actions to enhance competitiveness and foster sustainable innovation.

Future work will benchmark the identified needs and challenges against the EU Blue Bioeconomy Roadmap and the objectives of the European Green Deal to evaluate their alignment and strategic relevance. This will support the development of high-impact interventions that can accelerate transformation of marine biotechnology into a cornerstone of a sustainable and resilient Atlantic blue bioeconomy.

## Introduction

Patellid limpets represent important fishery, gastronomic, cultural, and ecological resources in the Macaronesia region. Recently, the limpet *Patella ordinaria* has experienced a severe population as a consequence of intensive anthropogenic pressure. Understanding and optimizing larval production is essential for both the success of aquaculture and the conservation of *P. ordinaria.* The goal of this study was to evaluate the resistance and resilience of early life stages of *P. ordinaria* to thermal stress.

## Material and Methods

Adult limpets were collected from Ponta do Garajau (Madeira) in February 2025. Assays were conducted in glass vials (10 mL) and glass beakers (500 mL) kept in water baths. The water baths were supported by the MOSS (Marine Organisms Stress Simulator) mesocosm facility (MARE-Madeira), being applied seven temperature treatments (12, 15, 18, 20, 22, 24, and 26 °C). before to be used for the assays. The assays focused on the influence of the temperature over: 1) the embryological development (22h incubation), 2) the larval development (48h larval culture), and 3) accumulative embryological and larval development (72h).

## Results and Discussion

Results of this study suggests that optimal temperature for larval production occurs between 15 and 18 °C, with reduced production outside this range (Fig.1). This highlights a narrow thermal tolerance and the sensitivity of early life stages to temperature stress. This study provides new insights into the species' sensitivity, which will be crucial for future considerations in limpet aquaculture.

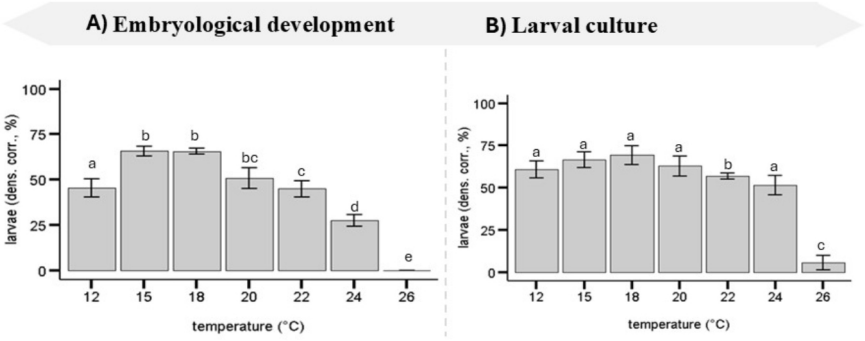

Fig. 1: The influence of temperature on larval production of *Patella ordinaria.* A) Ratio of viable larvae corrected by density during incubation. B) Ratio of viable larvae corrected by density during larval culture. Bars indicate average SD, and different letters indicate significant differences among the temperature ($p < 0.05$).

# DOSE-DEPENDENT EFFECT OF A BLEND OF NUCLEOTIDES ON ZEBRAFISH (*Danio rerio*) GROWTH PERFORMANCES

## Introduction

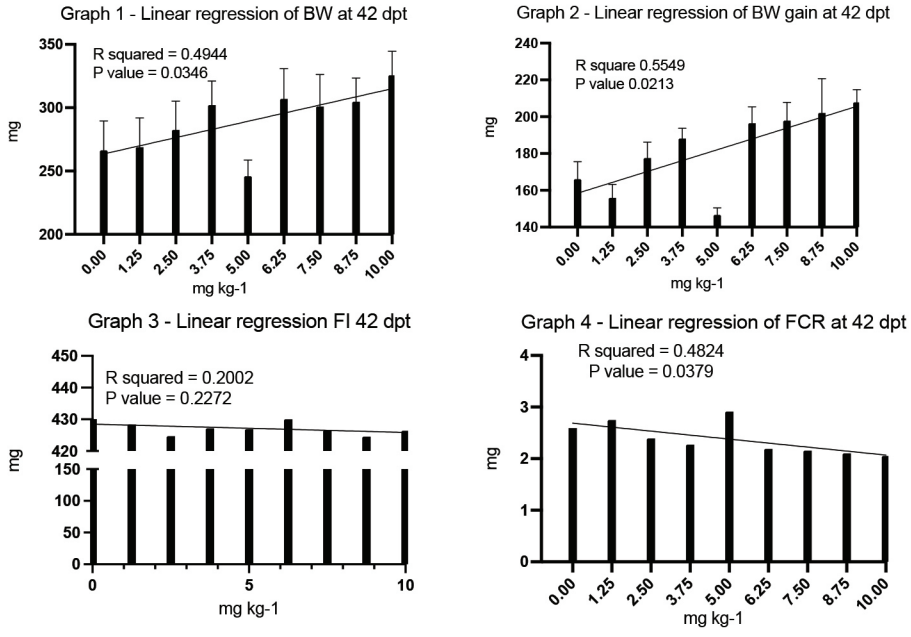
Challenges such as disease and environmental stressors represent a relevant threat to fish welfare and farm economic sustainability. Prophylaxis and good farming practices are important strategies to ensure fish welfare in farm conditions and reduce economic losses. Correct fish nutrition and feeding protocols are also key actions for a holistic approach to modern aquaculture production.

β-glucans, Mannano Oligo-Saccharides (MOS), antioxidants and other functional feed ingredients are more and more used in aquaculture. Unfortunately, their solely feed-inclusion is not sufficient to improve fish health and welfare and an appropriate combination of these ingredients is still necessary. This is also the case of nucleotides, a category of molecules characterized by different bioactivity and functions. Nucleotides are essential components of DNA and RNA and are involved in various physiological processes, including growth and immunity (Hossain et al., 2020).

The aim of this study was to investigate the dose-dependent effects of the feed inclusion of a specific blend of nucleotides, specifically formulated for aquaculture application, on fish growth performances. Zebrafish (*Danio rerio*) was used as animal model.

## Materials and methods

The study was carried out at the Zebrafish Facility of the Department of Veterinary Science, University of Pisa (Italy). Protocol and experimental design were approved by the Ethics Committee for Animal Welfare and Use of the University of Pisa and by the Italian Ministry of Health (code: B290E.N.LN2.).



*(Continued on next page)*

One hundred-eighty fish (102,3±26,43; m±ds) were uses to carry out the trial. The fish were divided into nine dietary treatments (20 fish per treatment), each one characterized by an increasing inclusion level of a specific bleand of nucleotide (Nucleo+ Marfeed, Miavit GmbH, Essen), as follow: 0, 1.25, 2.5, 3.75, 5, 6.75, 7.5, 8.75 and 10 g/kg. Water temperature was set at 28 °C, photoperiod was 12/12 h L/D and the feed was distributed *ad libitum,* 4 time per day (at 8, 11, 14 and 17), following the "five minutes rule" described by Lawrence (2007).

On days 0, 14, 28 and 42, each fish was slightly anesthetized (MS-222 Sigma, St. Louis, USA), photographed for further individual identification and weighted. Individual indentification was performed as already described by Fronte et al., (2021). Furthermore feed intake (FI) was measured, BW gain (BWg) calculated as difference between two following time points, and Feed Conversion Rate (FCR) calculated as FI/BWg.

The linear regression of final BW, BW gain, FI and FCR was performed to investigate the dose-reaponse effect of the considered treatments and parameters.

**Results and Discussion**

Excepted for FI, all the other considered parameters showed a significative dose-dependent effect. In detail, at the end of the experiment fish BW (Graph 1) was linearly enhanced (R squared 0.4922; P = 0.0346) by the dietary supplementation with the considered blend of nucleotides. Only exception was observed for the fish treated with 5 mg $kg^{-1}$ of nucleotides, which reached the lowest BW, with that not following the trend showed by the other groups. Similarly, also BWgain (Graph 2) linearly increased (R squared 0.5549; P = 0.0213). As already mentioned, FI (Graph 3) did not responded to the dietary supplementation (R2 0.2002; P = 0.2272), while FCR (Graph 4) linearly decrased according to the nucleotides supplementation (R2 0.4824; P = 0.0379).

In a previous study (Licitra et al., submitted for publication) carried out on a transgenic zebrafih model (*Tg(mpeg1:EGFP*)) an immunity enhancement effect was described (Licitra et al., submitted for publication). In present study, the same blend of nucleotides showed also a significant positive effects on fish growth. This effects seems to be linearly correlated to the feed inclusion rate. As described by Hossein et al. (2020), also other authors have already observed similar effects. However, the results of the present study suggest not toxic effect even at the higher dosage (10 mg $kg^{-1}$), but also that already 3.75 mg kg-1 may ehert significant effects on fish growth.

**Conclusion**

The aim of the present study was to define the possible efficacy of a blend of nucleotides, specifically formulated for aquaculture application, and the most appropriate dosage, on fish growth performances. The results showed a linear enhancement of the growth performances, starting from a dosage of 3.75 mg $kg^{-1}$ of feed. Also, no toxic effects were observed at higher dosages, the highest tested dosage (10 mg $kg^{-1}$) showing the best perfomances. Therefore, the results suggest a signicant efficacy of the tested blend of nucleotides, without evidences of possible toxicity effects.

# GROWTH PERFORMANCE AND INTESTINAL HEALTH OF RAINBOW TROUT *Oncorhynchus mykiss* PREVIOUSLY SUBJECTED TO INFLAMMATION WITH DEXTRAN SODIUM SULPHATE (DSS)

Stephane Frouel*, Frédérique Auger

Mixscience
2, Avenue de Ker Lann CS 17228
35172 Bruz Cedex - France
stephane.frouel@mixscience.eu

Aquaculture production has undergone remarkable growth during the past few decades, and it will continue to rise in the coming years to meet higher demand for safe, healthy and convenient seafood products. A lower usage of finite marine-harvested resources has been a major trend in the aquafeed industry. Grain and oilseed by-products are promising sources of protein and energy for aquaculture feeds. However, high dietary inclusion levels of plant proteins have often been associated to detrimental effects on growth, feed efficiency, intestinal dysbiosis and immune response, threatening the profitability of major aquaculture species.

Feed solutions that enhance digestive and metabolic processes have shown to be crucial to make these new feed formulation scenarios work, while reduce the environmental impact of aquaculture and promoting fish welfare. In the scope of this sustainable approach, Mixscience (France) developed a specific Phytogenics based solution that helps to reduce the negative impact of challenging feeds.

The aim of this study is to examine the effect of graded levels of feed additive (PHY) on the zootechnical performance, nutrient digestibility and intestinal mucosal health in rainbow trout (*Oncorhynchus mykiss*), previously subjected to a standardized inflammatory event with dextran sodium sulphate (DSS).

The Trout trial includes 5 treatments.
- A positive control **(PC)** = optimal diet for the targeted fish
- A negative control **(NC)** with lower levels of digestible protein and digestible energy due to fish meal replacement by challenging ingredients derived from defatted soybean meal and sunflower meal, which tend to reduce digestibility and negatively affect intestinal integrity.
- 3 additional diets, based on the NC formula, supplemented with the tested product **(PHY)** at a dose of 50 **(PHY50)**, 100 **(PHY100)** or 200 **(PHY200)** g/Tonne of feed.

The trial comprised 3 experimental phases:
- Phase I: A chemically induced intestinal inflammation using a diet with 1% dextran sodium sulphate (DSS) on the overall fish population for 10 days
- Phase II: An experimental feeding of the 6 experimental feeds over 86 days, to assess their effect on the growth performance and restoration of intestinal health criteria
- Phase III: a measurement of apparent digestibility of nutrients

The results indicate very clearly that in trout, compared to an optimal feed (PC), a challenge feed (NC) in which part of the fish meal has been replaced by plant ingredients and stress inducers, induces negative metabolic reactions: increase in systemic inflammatory status, expressed at blood and fecal level, a decrease in nutrient digestibility **(Figure1).** This outcomes in lower feed efficiency, and performance of fish **(Table 1).** The negative impact of a challenging feed can be compensated by specific phytogenics that activate key metabolic activities to save energy and maintain overall resistance that limits dysbiosis and intestinal disorders under stressful conditions and helps maintain a healthy optimal feeding efficiency and an overall fitness of the host. The results consolidate the results obtained in 2023 with Seabream. The optimal dose demonstrated for seabream of 200 g/T of feed is confirmed for trout. A positive effect is observed at a lower dose of 100 g/T of feed. A dose of 50 g/T is not sufficient to have a positive effect.

# INNOVATIVE PROTEIN CONCENTRATES FOR SUSTAINABLE AQUACULTURE: THE PROVEA RANGE

Julien Gouvis*, Frédérique Auger et Stephane Frouel

Mixscience, AVRIL
2, Avenue de Ker Lann CS 17228
35172 Bruz Cedex - France
julien.gouvis@avril.com

The aquaculture industry is rapidly expanding and plays a crucial role in global food security. However, it faces significant challenges in terms of sustainability and nutrition due to a shortage of the marine protein sources.

To address these challenges, the Provea range focus on developing innovative protein concentrates from plant-based sources such as sunflower, faba bean, and pea. These concentrates, produced by Mixscience, a subsidiary of the Groupe Avril, aim to improve the nutritional composition and the digestibility of aquatic species, and to provide sustainable protein alternatives to formulate aquafeeds.

The Provea range offers a sustainable and nutritionally superior alternative for aquafeeds, contributing to the industry's growth and environmental goals. By leveraging locally sourced plant-based proteins, we can promote sustainable practices and support the development of a more resilient aquaculture sector.

This poster presents the results of our research on the nutritional composition, digestibility, and sustainability of the Provea range protein concentrates, as well as the benefits in fish farming.

**Nutritional Composition:** The protein concentrates have high protein content, ranging from 50-60%, which is essential for the growth and health of the fish. They also have a fat content of 3-6%, which helps in maintaining the overall health of the fish. The fiber content is moderate, less than 12%, ensuring good digestibility, and the moisture levels are around 8-10%, which helps in maintaining the stability and shelf life of the product.

**Digestibility:** The protein digestibility in trout is high, with values around 85-87%. This indicates that the protein concentrates are efficiently utilized by the fish, promoting growth and health. High digestibility is crucial for ensuring that the nutrients are absorbed effectively, leading to better feed conversion ratios and overall performance of the fish.

**Sustainability:** The project emphasizes reducing the carbon footprint by using locally sourced raw materials and adopting environmentally friendly processing methods. By supporting local agriculture and reducing dependence on imported fishmeal, the project contributes to the sustainability of the aquaculture industry. The use of plant-based proteins not only supports environmental goals but also promotes the development of a more resilient and sustainable aquaculture sector.

**Conclusion:** The use of these innovative protein concentrates in aquaculture feed offers several benefits, including improved optimization of formulation cost, animal nutrient digestibility, reduced environmental impact, and enhanced traceability of feed ingredients.

Continued research and development are essential to optimize the formulations and expand the applications of these protein concentrates in aquaculture. Future studies will focus on the impact on global fish performance and health

# OVERCOMING CHALLENGES IN IMPLEMENTING NOVEL FEED INGREDIENTS: INSIGHTS FROM CLOVER USAGE

V. Fuchs*[1], M. Weiss[1], C. Dolgow*[2]

[1]Alfred Wegener Institute Helmholtz Center for Polar and Marine Research, Am Handelshafen 12, 27570 Bremerhaven, Germany
E-mail: Vanessa.Fuchs@awi.de

## Introduction

The pressing need to identify appropriate alternative resources to support aquafeed sustainability demands alternatives for resources that cannot directly be used for human food. Clover, a legume grown frequently as catch crop, was chosen as a novel non-food protein feed ingredient for the yellowtail amberjack (*Seriola lalandi*). The cultivation of clover grass can enhance soil quality, farm profits and the product is harvested in appropriate amounts to serve as a reliably available, sustainable, alternative protein ingredient for aquafeeds.

Its applicability in aquafeeds was tested

1. In a digestibility trial with the Yellowtail amberjack
2. In pellet production trials to test physical processing behavior.

## Material and Methods

Digestibility trials were conducted in a recirculating aquaculture system as described by Glencross et al. (2007). The reference diet was formulated to meet nutritional requirements of *S. lalandi* (Table 1) (IAFFD and pers. comm. Infinite Sea GmbH). The test diet was prepared by adding 3 parts clover gras protein concentrate to 7 parts of the reference diet mash on weight basis. Additionally, one test feed contained amylase to test its efficiency to support starch digestion in *S. lalandi* and one contained psyllium to test its effect on faeces properties. Each diet was fed to tank triplicates containing 20 fish.

Results presented will include digestibility of Clover grass, details of *S. lalandi* growth and health as well as rheological parameters of faeces.

## Pellet Production

A twin-screw extruder (ZK 20/40 P, Collin Lab & Pilot Solutions) was used to produce all experimental diets. The pellets were produced at a constant mass flow rate of 5 kg/h and with a 2 mm die. The screw speed (200, 400 rpm) and the temperature profile (Table 2) was varied during production.

The pellets were cut with a pelletizer (ELG 10, Econ GmbH) and dried continuously using an infra-red drum dryer (B.IRD Machinery Stricker GmbH). During measurement, the specific mechanical energy [SME] (Wh/kg), the pressure (bar) and the melt temperature (°C) were determined and documented using Fecon software.

## Pasting properties of pellets

The gelatinisation was determined using a Global Rheological Solution Viscosimeter (Australia) according to the ICC 169 method. The sample was mixed with water to form a 6 % starch suspension (dry substance) and placed in a sample beaker. Defined heating and cooling cycles were carried out for analysis. The measurement was carried out applying a heating cycle from 30 °C to 93 °C. A temperature of 90 °C was maintained for 20 minutes. The sample was then cooled to 50 °C and held again for 20 minutes. The stirrer speed was 75 rpm. The heating rate was 1.5 °C per minute. Global Rheological Solution software was used to determine gelatinisation temperature, highest observed viscosity, breakthrough viscosity, final viscosity and restoring viscosity.

**Introduction**
The paradigm of feed formulation has shifted to address sustainability issues in aquaculture, primarily due to concerns about the environmental impact of traditional fishmeal-based diets (Tacon et al., 2022). However, this approach introduces unprecedented complexity in fish feeds, making it necessary to assess the cost-benefit of incorporating these new sustainable resources. As a result, plant-based proteins are increasingly utilised as replacements for fishmeal in aquaculture feeds, yet their impacts on intestinal immune, barrier, and functional properties remain unclear. We examined how replacing 50% of fishmeal with wheat flour (D1) or wheat gluten (D2) influences growth performance, as well as intestinal gene expression and physiology in juvenile *Seriola dumerili*.

**Materials and Methods**
Juvenile Seriola dumerili (~55 g initial mean body mass) were fed a premium control diet (CTRL) or experimental diets D1 or D2 for three months. Growth performance and feed efficiency were monitored. Anterior intestinal tissue was sampled for Ussing chamber measurements (Fuentes et al., 2025) of transepithelial resistance (Rt) and short-circuit current (Isc). Gene expression of immune-related (infg, il34), transport (slc15a1, slc15a2, slc15a4), and integrity-related (vil1, tjap1, tjp1a, tjp1b, cldn11, cldn12) markers was quantified by qPCR.

**Results**
Both D1 and D2 significantly reduced final mean weight, specific growth rate (SGR), and feed efficiency compared to CTRL ($p<0.001$), with no significant difference between D1 and D2 (Fig. 1). Ussing chamber assays showed that anterior intestinal Rt was significantly lower in D1 and D2 versus CTRL throughout the assay ($p<0.0001$), indicating impaired barrier integrity. Similarly, Isc was significantly different in D1 ($p = 0.0059$) and D2 ($p = 0.0145$) compared to CTRL, reflecting decreased active ion transport and the onset of a predominant secretory process (Fig. 1). At the molecular level, D1 significantly increased *infg* ($p = 0.0086$), while downregulating *vil1* ($p = 0.0002$) and *cldn11* ($p = 0.03$), indicating inflammation and epithelial remodelling. D2 also significantly decreased *vil1* ($p < 0.0001$) but increased *tjp1a* ($p = 0.0144$), while reducing *Slc15a2* ($p = 0.0333$) and *il34* ($p = 0.0245$), suggesting impaired immune homeostasis without overt inflammation. Notably, in both D1 and D2, *slc15a4* showed a non-significant tendency to increase, which may reflect a compensatory response to epithelial stress or altered immune signalling.

**Discussion**
These findings highlight distinct intestinal and physiological responses to diets containing wheat flour and wheat gluten. Both diets impair growth and feed efficiency, and reduce intestinal barrier function and active transport, indicating functional compromise of the mucosa. D1 triggers strong pro-inflammatory and epithelial remodelling responses, likely caused by fibre and antigenic components, which compromise barrier integrity. In contrast, D2 effects suggest a subtle decrease in IL34 and macrophage support, without causing overt inflammation. The contrasting regulation of SLC15 transporters and tight junction genes emphasises the complex interactions between diet composition, epithelial integrity, immune surveillance, and functional outcomes in the fish gut.

*(Continued on next page)*

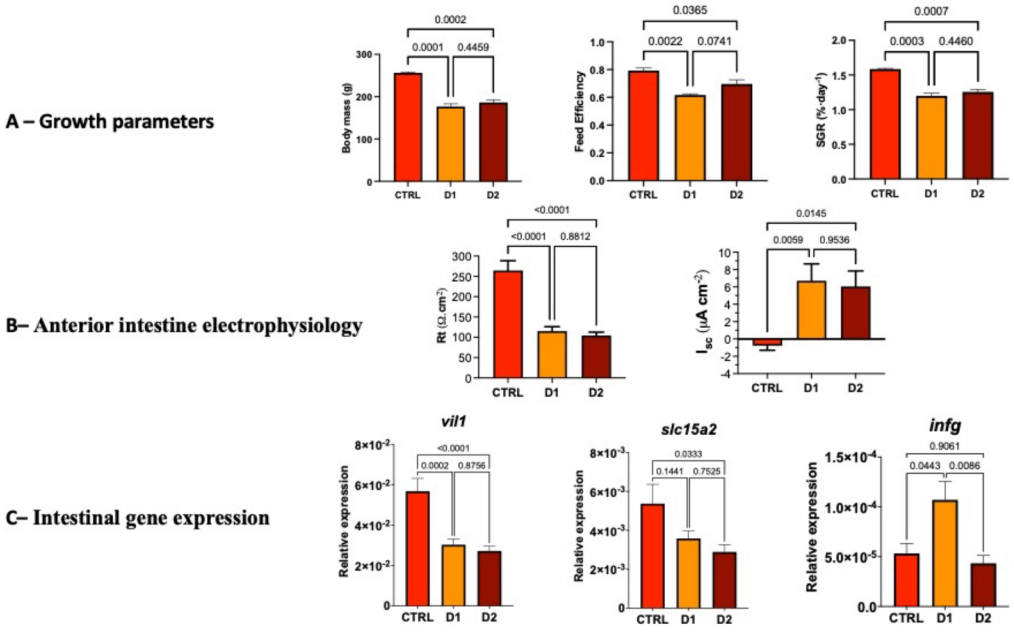

**Figure 1**. Effect of different diets on: A - growth parameters (final mean weight, feed efficiency (FE) and specific growth rate (SGR). B - anterior intestine electrophysiology (tissue resistance (Rt, Ω $cm^{-2}$), and short circuit current (Isc, μA $cm^{-2}$). C - intestinal expression of integrity- (*vil1*), transport- (*slc15a2*), and immune-related (*infg*) genes. Columns represent the average ±SEM (n=12); Diets: CTRL, D1, D2. Statistics were one-way ANOVA, complemented with a Tukey's post-hoc test.

## Introduction

The intensification of aquaculture has driven the search for nutritional strategies that not only ensure the efficient growth of cultured species but also meet sustainability and functionality criteria (Quagliardi *et al*., 2024). In this context, the reformulation of feeds through the incorporation of alternative ingredients and additives with bioactive properties has taken a central role. One of the challenges associated with the partial or total replacement of fishmeal by plant-based sources lies in the adverse effects these ingredients can have on the digestive physiology of fish, due to the presence of antinutritional compounds that interfere with nutrient digestibility, alter intestinal morphology, and in some cases, affect feed efficiency and the quality of the final product (Seibel *et al*., 2022). In response to this issue, the use of functional additives capable of mitigating these limitations has garnered increasing interest. Among this group, biochars represent an emerging option with notable potential, derived from slow pyrolysis processes of lignocellulosic materials, such as agricultural residues, which give them a microporous structure and high adsorption capacity. These characteristics enable their application as modulators of the digestive environment by reducing undesirable metabolites and promoting more stable conditions in the gastrointestinal tract. Furthermore, it has been suggested that their inclusion in the diet may influence nutrient digestion and absorption, potentially generating indirect effects on protein and lipid deposition in muscle tissue, which is particularly relevant in commercially important species. In the case of sole (*Solea senegalensis*), a benthic species of high value in European aquaculture, knowledge about the physiological effects of biochar during early developmental stages is still limited, making it necessary to further explore its potential role as a functional additive in feeds formulated to improve digestive functionality and muscle quality during the juvenile phase.

In light of all these considerations, the main objective of this study was to evaluate the effect of the inclusion of cherry tree biochars in feeds with a high percentage of plantbased meals for juvenile sole on growth performance, muscle tissue proximate composition, and digestive functionality in juvenile sole.

## Material and Methods

To carry out the feeding trial, three experimental diets were formulated: a control diet (CT), based on plant meals; a B0.25 diet, supplemented with 0.25% biochar; and a B0.5 diet, supplemented with 0.5% of the functional additive. At the end of the feeding trial, muscle samples were collected to determine their proximate composition, and intestinal samples were taken to evaluate the activity of pancreatic secretion enzymes (trypsin, chymotrypsin, and total alkaline protease) and intestinal secretion enzymes (leucine aminopeptidase and alkaline phosphatase).

## Results and Discussion

The activity of digestive enzymes provides valuable information about the nutritional status of fish. Figure 1 shows the results obtained for digestive enzyme activity. In general, a decrease in the activity of pancreatic secretion enzymes was observed in B0.25 experimental group compared to the other groups. Meanwhile, fish fed B0.5 experimental diet showed the highest values of alkaline phosphatase activity, which could be associated with an increase in intestinal absorption capacity in these fish. However, although these results indicate a modification in the digestive functionality of the fish, further research is needed to draw more robust conclusions.

Likewise, the analysis of the proximate composition of the muscle in juvenile sole fed the different experimental diets showed a significant increase in lipid content in those fish that received the biochar-supplemented feeds, which could indicate a modification of lipid metabolism mediated by these functional additives.

## Introduction

European aquaculture emphasizes new functional feeds as a strategy to maintain animal welfare and reduce reliance on antimicrobials. The use of medicinal plants holds strong potential as alternative to antibiotics and immunoprophylaxis in aquaculture. *Artemisia annua* is an annual herb species widely known for treating malaria (Soni et al., 2022), with reported benefits in fish including enhanced immune responses and reduced stress markers (Hoseini et al., 2022), although effects depend on dose and formulation. *A. annua* feed supplements are expected to improve fish health and growth, making them promising candidates for the development of functional and health-promoting feed additives in the aquaculture sector. Lipopolysaccharides (LPS) are commonly used to induce strong inflammatory responses in fish, making them useful for evaluating the efficacy of functional feeds in modulating immune and metabolic responses. The main objective of this study was to assess the effect of an *A. annua*-supplemented diet on *Sparus aurata* juveniles subjected to a LPS challenge focusing on growth performance, blood parameters, and muscle lipid composition.

## Material and methods

Juvenile gilthead seabream (n = 144) with an average weight of 47.18 ± 6.60 g were randomly distributed into 12 1-$m^3$ polyethylene tanks and assigned to either a commercial diet (C, control; 6 tanks), or the same diet supplemented with 30 g/kg of powdered dried *A. annua* leaves (A, experimental; 6 tanks). Six fish per tank were randomly tagged with microchips. Fish were fed 3% of their total biomass daily. After 37 days of feeding, three tagged fish per tank were intraperitoneally injected either with 5 mg/kg body weight of *Escherichia coli* LPS (3 tanks per diet), or an equivalent volume of phosphate-buffered saline (PBS; 3 tanks per diet), resulting in four experimental groups: C, A, CLPS and ALPS. Forty-eight hours post-injection, fish were sacrificed for intermediate sampling. Subsequently, the dose of *A. annua* in the A diet was reduced to 10 g/kg, and the same sampling procedure was repeated after 62 days (final sampling). At both samplings, blood was collected using heparinised syringes for parameter analysis, while muscle total lipid (TL) and fatty acid (FA) composition were determined. Survival and growth were monitored throughout the experiment.

Table I. Specific growth rate (SGR), blood parameters, and muscle total lipid (TL) content of *S. aurata* under the experimental treatments at both sampling points.

D, diet; I, injection; In, interaction. * Significant differences (Two-way ANOVA). Results are medians ± standard deviation (n= 9)

*(Continued on next page)*

**Results**

Fish survival (94-100%), TL, and FA composition of muscle was similar across all dietary treatments. However, specific growth rate (SGR) was primarily affected by the diet at both sampling points, while weight gain was affected by both diet and injection at the end of the experiment, with A diet and LPS injection showing the worst results ($p<0.05$). Additionally, viscerosomatic (VSI) and hepatosomatic indices (HSI) also decreased in fish fed the A diet ($p<0.05$). Regarding blood parameters, haematocrit and total plasma protein were markedly reduced in fish fed diet A at both samplings, while cholesterol decreased at the midpoint and haemaglobin at the end of the experiment (Table I). At the end of the experiment, haematocrit and triglycerides increased in response to LPS injection, while interaction between diet and injection had a significant effect on cholesterol, triglycerides, and haematocrit levels ($p<0.05$).

**Discussion and conclusions**

Although *A. annua* has been reported to improve growth in some species, it reduced growth and both VSI and HSI in our study. Similar results were reported for *S. aurata,* with *Artemia arborescens* supplementation, attributed to imbalances in nutrient digestion and absorption (Tzortzatos et al., 2024). Negative effects on growth and haematocrit were detected at the intermediate sampling, and although the dosage was readjusted, it was insufficient to mitigate them. The reduction in haematocrit and haemoglobin may indicate erythrocyte hemolysis and anemia, contrary to benefits reported in common carp (Hoseini et al., 2022). Medicinal plants like *A. annua* contain compounds that can induce both haemolytic and anti-haemolytic reactions in human erythrocytes (Sohou et al., 2024), though the role of artemisinin derivatives in fish remains unclear. At the final sampling, haematocrit increased in fish fed the A diet following LPS injection compared to PBS, possibly due to splenic contraction and the release of stored erythrocytes described during acute stress (Fazio et al., 2015). *A. annua* has been described to protect against lipid oxidation in common carp (Hoseini et al., 2022), but its direct effect on fish FA profiles is yet to be studied. In our work, TL and FA composition were similar across treatments. These findings suggest that *A. anua* supplementation may negatively affect growth and blood parameters in gilthead seabream. Further studies with varied doses under controlled conditions are needed to determine the optimal range for beneficial application, if any.

## Introduction

Improving the health of farmed species by defining optimal welfare conditions is a major current challenge in aquaculture. Many species form social hierarchies, and the dominant-subordinate relationship can cause stress, which may impact the animals' growth and well-being, directly affecting productivity. The gilthead seabream, *Sparus aurata*, can change its body colour in response to environmental changes and as a signal of behavioural strategies. This colour change may also influence aggressive behaviour (Batzina & Karakatsouli, 2014). In this study, the effect of tank colour on the growth, colouration and behavioural patterns of juvenile seabream was evaluated to better understand the species' comportment strategies.

## Material and methods

A total of 56 *Sparus aurata* juveniles (initial weight: 232.10 ± 50.90 g) were tagged with microchips and randomly distributed among eight 1 $m^3$-polyethylene tanks with two background colours: black (B) or white (W) (four tanks per colour). Fish were fed a commercial diet *ad libitum* five days per week. After 31 days, fish were subjected to colour sampling in 80 L filming tanks equipped with an underwater camera and a colour checker. Each fish was transferred either to a filming tank of the same colour (control) or of the opposite colour (experimental). Consequently, fish from black tanks were transferred to white tanks (B_W), whereas fish from white tanks were transferred to black tanks (W_B). Following a 5-minute video recording, fish were moved to a recovery tank and then returned either to their original (control) or experimental tanks, where they remained until the end of the trial (day 81). Still images were extracted from minutes 0-1 (T1) and 4-5 (T2). Colour data were standardized and RGB values (Red-Green-Blue model) were converted to HSV using the grDevices R base package (Rodriguez-Barreto *et al.*, 2019), allowing for the calculation of Hue (pure colour), Saturation (intensity) and Value (brightness).

Aggressive behaviour was recorded using underwater cameras during feeding sessions, both before and after colour sampling. The 2-min videos were analysed to quantify aggressive acts (charging and chasing, fighting, and circling). Fish survival and growth were monitored throughout the experiment.

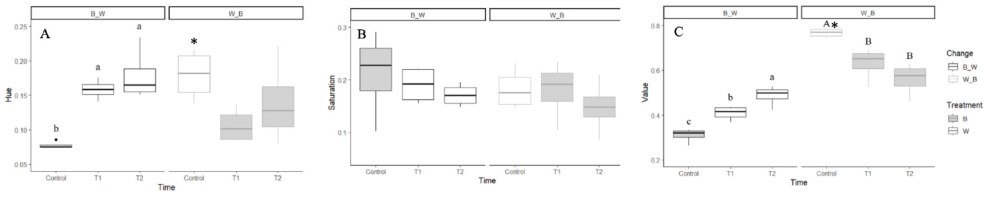

**Fig. 1.** Hue (A), saturation (B), and value (C) in control and two time periods (T1, 0-1 min; T2, 4-5 min). Results are medians ± SD (n= 4). B, black tanks; W, white tanks; B_W, fish transferred from black to white tanks; W_B, fish transferred from white to black tanks; ·, outliers; * indicates significant difference between B and W tanks within the control treatment ($p<0.05$, t-test); Different letters (a, b, c and A, B) indicate significant differences among control, T1, and T2 within the same colour-change group ($p<0.05$, one-way ANOVA).

*(Continued on next page)*

**Results**

Fish survival, growth, and colour intensity (saturation) were not affected by the tank bottom colour. However, in the control treatment, hue and value were lower in B tanks than in W tanks. After the tank colour change, fish from B_W showed higher hue values in both time periods (T1 and T2) compared to the control, whereas W_B fish showed no differences across treatments (Fig. 1). Value was lowest in the control and highest in T2 treatment for B_W. In W_B, the control showed the highest value. At T2, no significant colour differences were found between fish in B and W tanks. Lastly, the number of charges and chases showed no significant differences, and no fighting or circling behaviours were observed in any videos.

**Discussion and conclusions**

This study showed that juvenile *S. aurata* can be reared in either black or white tanks without negative effects on growth or survival. Fish colour intensity (saturation) was similar regardless of tank colour, although fish from B tanks were darker (lower hue) than those from W tanks, consistent with Wang et al. (2020) in red tilapia. Hue changed immediately after transfer from B to W tanks (B_W), reaching its final value within the first minute, whereas brightness (value) increased more slowly, stabilizing after 4-5 minutes. When fish were transferred from W to B tanks (W_B), brightness changed rapidly, whereas hue remained stable. Similar results were found by Wang et al. (2020) in red tilapia. No significant differences in hue or value were found between B and W tanks after five minutes (T2), suggesting that this period is insufficient for complete colour adaptation, although a trend toward adjustment was observed. The immediate response is likely mediated by the neuroendocrine system reacting to handling and environmental stress, whereas full colour adaptation may depend on slower, long-term physiological processes (Wang et al., 2020; MacLean, 2021).

Although background colour has been shown to affect aggressive behaviour in fish (MacLean, 2021), no differences in charging or chasing were found in this study, and neither fighting nor circling were observed—possibly due to the short recording time.

# A MACHINE LEARNING-DRIVEN EARLY WARNING SYSTEM FOR CRYPTOCARYONIASIS IN MARINE AQUACULTURE

J. Galindo-Villegas[c]*, X. Xie[a], B. Zhang[a], X. Wang[a], Y. Jiang[a], K. Buchmann[b], S. Zhou[a], Y. Li[a], and Fei Yin[a#]

[*] E-mail: Jorge.galindo-villegas@nord.no

**Introduction**: Disease outbreaks, particularly cryptocaryoniasis caused by the ciliate *Cryptocaryon irritans*, pose significant barriers to sustainable marine fish aquaculture, undermining productivity, profitability, and biosecurity. Despite its impact, early warning tools for parasitic disease tools leveraging advanced technologies remain underdeveloped.

**Material and Methods**: We developed a machine learning (ML)-driven early warning system for cryptocaryoniasis, integrating seven years of outbreak surveillance data (n=429 events from 2016–2023) with 17 high-resolution oceanographic and environmental predictors selected for their influence on parasite life cycles across coastal China. Five supervised ML models: logistic regression (LR), support vector machine (SVM), random forest (RF), XGBoost (XGB), and artificial neural network (ANN), were trained using cross-validation and benchmarked in commercial open-sea cages and recirculating aquaculture systems (RAS).

**Results**: The RF model achieved the highest sensitivity (98.6%), with RF and XGB excelling over (F1 scores: 0.93 and 0.938, respectively), identifying stocking density, water temperature, salinity, pH, and novel predictors like silicate and nitrate as key risk factors. The resulting predictive engine was deployed as a web-based platform, freely accessible online via open-source environmental data, delivering weekly, spatially resolved outbreak forecasts. Field validation, across 12 open-sea cage events and weekly RAS monitoring, confirmed strong predictive accuracy (91.67% in sea cages; 87.5% in RAS), revealing seasonal and latitudinal trends in disease dynamics.

**Conclusion**: This study establishes a robust, scalable framework for real-time disease forecasting in marine aquaculture, adaptable to other aquatic pathogen-host species to support parasite surveillance and precision health management across diverse global aquaculture systems. While further validation with larger datasets and integration of pathogen and host data will enhance future models, this system provides a flexible foundation for advancing disease control in aquatic environments.

# EVALUATION OF *Spirulina* AND *Azolla* AS PARTIAL REPLACEMENT FOR FISHMEAL IN FORMULATED DIET FOR KOI CARP (*Cyprinus carpio* var. *koi*) REARED IN AN AQUAPONIC SYSTEM

Wenresti Gallardo*, Fahad Al-Mashrafi, Abdullah Al-Alawi, Ahmed Al-Souti

Department of Marine Science and Fisheries
College of Agricultural and Marine Sciences
Sultan Qaboos University
Sultanate of Oman
Email: gallardo@squ.edu.om

Fishmeal is commonly used as a protein source in aquaculture feeds; however, there is a growing need to reduce its use due to sustainability concerns. This study evaluated the proximate composition (crude protein, lipid, fiber, ash, and nitrogen-free extract), palatability, attractability, and water stability of a formulated diet using *Spirulina* and *Azolla* as fishmeal replacements, as well as the growth performance of koi carp (*Cyprinus carpio var. koi*) cultured in an aquaponic system. Three different fishmeal replacement levels were tested: 30% and 50% replacement with *Spirulina* and *Azolla*. The parameters measured included weight gain rate (WGR%), specific growth rate (SGR%), survival rate (%), feed efficiency (FE), and feed conversion ratio (FCR). Water quality parameters—temperature, dissolved oxygen, pH, ammonia, nitrite, and nitrate—were monitored weekly. There were no significant differences ($P > 0.05$) in the proximate composition, attractability, palatability, water stability, or growth performance between the diets containing *Spirulina* and *Azolla* and the control diet. Similarly, there were no significant differences ($P > 0.05$) in the measured water quality parameters. The results indicate that *Spirulina* and *Azolla* can successfully replace up to 50% of fishmeal in the formulated diet for koi carp without negatively affecting growth performance or water quality in an aquaponic system.

# ONE STEP FURTHER TOWARDS A BETTER SOCIAL PERCEPTION OF SALMON FARMING IN CHILE PILOT OF A REGULATORY AND ENVIRONMENTAL COMPLIANCE PROGRAM
